Preface to the seventh edition

Since the publication of the 6th edition of the Textbook in 2015, there have been many events and changes that have impacted public health and which public health must address. Although we have made progress in many areas globally new challenges, often unanticipated, have emerged or re-emerged that compromise known and effective public health interventions. Public health now operates in a world of rapid communications and social media which, though very influential, is not monitored for veracity and, thus, can be counterproductive for public health goals (see Chapter 4.3). The rise in machine learning and artificial intelligence are redefining personal and public health practice globally and could be an important bridge to address health disparities particularly in settings where health infrastructure and resources are limited or lack of affordability could sow greater divisions even in industrialized countries.

Several new infectious disease agents have emerged for which we must develop innovative interventions (Chapter 8.11). These include Zika virus, the Middle Eastern Respiratory Virus (MERS), acute flaccid paralysis (AFP), for which an aetiologic agent is currently unknown, and SARS-CoV-2 (Chapter 8.17). Further there has been a resurgence of measles and mumps, diseases which we thought we had largely under control through high immunization coverage. The resurgence of these diseases especially in industrialized countries are not the result of genetic or biologic changes in the agents or poverty, but of changes in the social and political environment that include challenging the use of vaccines. Thus, infectious disease control persists as an important global problem (Chapters 8.13–8.17, 11.3, and 11.4). Mathematical strategies for modelling control of infectious diseases are being increasingly used (Chapter 5.17).

For the first time in recorded history human lifespan is not expanding in many parts of the world. The reasons for this slow down are not fully understood but may be related to issues surrounding access to healthcare,

unhealthy lifestyles (including lack of exercise), the drug epidemic (precipitated by overprescription of painkillers), and an increase in suicide and obesity (Chapters 8.4, 8.5, and 9.2).

While in industrialized countries understanding of and models of healthcare for their ageing populations continue to evolve, in Africa there is a youth bulge resulting from reduced life expectancy in adults primarily as a result of large numbers of adult AIDS-related deaths in the 1990s and early 2000s and the success of the post-2000 PMTCT efforts. These demographic transitions between countries have important ramifications for social cohesion within and between countries.

Politically there has been a shift to conservatism. For example many of the regulations safeguarding the environment are being reversed, particularly in the United States (Chapters 2.2 and 7.1). The impact of these roll backs will exacerbate the problem of climate warming, perhaps currently the major public health issue facing earth (Chapter 2.9). Increasing warming of the earth will impact food supplies, habitable areas, and cause major shifts in the distribution of infectious agents and the vectors which carry many of them. The outcomes of climate change are already apparent in the increasing number of floods and fires plaguing many countries. Unfortunately the issue of climate change has become politicized to the detriment of the global population.

Although the global economy is currently doing well, on average, the disparity between the rich and the poor is widening as the rich get disproportionally richer (Chapter 2.4). This disparity is reflected in the increasing number of individuals who are homeless. Finding shelter and counselling and support services for them has become a political problem stemming from the attitude ‘not in my back yard!’ Inequitable distribution of income which has resulted in increasing levels of poverty remains the major cause of ill-health globally limiting access to healthcare, academic achievement, and a healthy lifestyle (Chapters 2.3, 2.4, 2.5, and 3.3).

Although safe working conditions are still an issue in high-income countries, transnational corporations have shifted manufacturing from high-income countries to low-income countries, where costs are lower. The problem is greatest in low- and middle-income countries in which regulations to promote worker safety and health are minimal because of the need to keep labour costs low. Governments in these countries are reluctant to implement expensive regulations which increase cost, making their

goods less competitive (Chapters 7.4 and 7.5). Worker safety adds to the cost of manufacturing, thus occupational health and safety legislation gets relatively little government attention in poor countries.

Migration from low- and middle-income and/or countries where conflict is high has increased as reflected in the number of individuals seeking asylum in high-income countries. Unfortunately the destination countries have been reluctant to accept the migrants. Underlying this problem is racial bias. As a result many individuals have died and families been disrupted. Violence and hate crimes are increasing, often targeting individuals of different religions or ethnicity. War in the eastern Mediterranean countries has persisted creating refugee camps which promote infectious, social, and psychologic problems. The problem of violence against women persists. Intimate partner violence affects as many as 35–40% of women in some regions of the world. Stigma has complicated disease control programmes, particularly for HIV/AIDS (Chapters 8.13, 8.18, 9.5, 9.6, and 10.2).

Increasing resistance to drugs especially for tuberculosis and gonorrhoea, is now a major problem (Chapters 8.12 and 8.14). We are out of drugs for multidrug resistant tuberculosis and increasingly gonorrhoea. The origin of this growing resistance to drugs is overprescription and commercial use of drugs (e.g. prescribing antibacterial drugs for viral infections) and the widespread use of drugs in the food industry).

Technology has facilitated many interventions but has also created many unanticipated public health problems. The internet and social media are potentially powerful tools for health education and dissemination of public health interventions (Chapter 4.3). However, they can also be used to undermine public health programmes. There are effective vaccines for measles, mumps, and many other infectious diseases. Unfortunately, social media in particular has been used to disseminate false information asserting that vaccination of children can cause autism and other health problems. As a result, many mothers are refusing to vaccinate their children, thus lowering the prevalence of immune individuals below the level of herd immunity required to stop transmission. For example, measles and mumps had been virtually eliminated in North America and Europe by the beginning of the twenty-first century. Due to parents' reluctance to vaccinate children and assumptions that these diseases were no longer a problem, thousands of cases of measles are occurring in North America,

Europe, and elsewhere with a significant number of deaths, especially in Samoa and Ukraine where both cases and deaths have soared. Although California and several other states have mandated immunization as a requirement for entry into school, mothers are putting pressure on physicians to write waivers for their child. Many physicians do not recognize their public health responsibility not to accede to these requests explaining to the mothers that they may actually be putting their children at greater risk of disease and more serious complications if infected at an older age. Other problems have blocked the programme to eradicate polio in the last remaining countries in which they persist. The killing of vaccinators in remote areas of Pakistan and Afghanistan has posed a new challenge to achieving sufficient levels of immune individuals to halt spread and achieve eradication. Thus, it has been necessary to use other strategies, such as mass vaccination days, to achieve a high level of herd immunity in these areas.

Positive mental health is essential for an individual to achieve a healthy productive life and is the foundation for the effective functioning of a community (Chapter 8.7). Yet, it has been estimated that in some populations as high as 25% of total disability is due to mental health disorders and is a major cause of suicide. Among adolescents, in developed countries the proportion diagnosed with mental problems may be as high as 50%. However, the amount and proportion of health dollars spent on mental health is low, particularly in lower- and middle-income countries. The lack of funding translates into a paucity of health professionals capable of treating mental illness.

The advancement of technology in the field of genetics and genomics has resulted in new opportunities for studying the genetic correlates of disease (Chapter 2.6). However, advanced technology such as the altering of genes in human foetuses has also introduced complex ethical issues about the future direction of genetic analysis and intervention (Chapter 3.2).

The rapid rise of the internet and social media presents a serious challenge to the effective implementation of public health interventions (Chapter 4.3). For example, the development of websites to promote commercial and recreational sexual activities plays a role in the current epidemic of several sexually transmitted infections. Future generations of public health professionals will need to develop effective strategies using the internet and social media to counter misinformation being disseminated by them and to promote public health.

The Sustainable Development Goals provide an opportunity to enable full development of healthy nations and communities from birth throughout life encompassing communicable, non-communicable diseases; other causes of morbidity and mortality; gender, economic, and racial disparities and emerging and re-emerging issues; environmental and non-environmental drivers of ill-health; spatial planning, and a basic human rights approach to health and well-being. The recent expansion and growth in social movements globally reflect that citizens are becoming more engaged and want more influence in decisions and actions that shape and influence their lives.

As the 7th edition of the *Oxford Textbook of Global Public Health* goes to press the world is experiencing a pandemic caused by SARS-CoV2 which, only 4 months after it was first recognized in Wuhan, China in early January 2020, has already caused over 3.25 million cases and over 226,000 deaths. Thus far, the only intervention that has been demonstrated to mitigate the pandemic has been social distancing resulting in global quarantining of the population. The impact on the global economy has been devastating. It is clear that the SARS-CoV2 pandemic will have a major impact on public health, the economy, and the way society functions globally in the future (Chapter 8.17).

As in previous editions we have divided the 7th edition of the *Oxford Textbook of Global Public Health* into three volumes—the scope of public health, the methodologies utilized by public health professionals, and the practice of public health. As in previous editions of the *Oxford Textbook of Global Public Health*, the intention of the 7th edition is to provide insights into the range and character of health problems challenging public health and effective strategies to address them as well as to anticipate what the challenges to public health will be in the future. There will be a diversity of views about how to achieve this goal, but hopefully agreement on what the goals are. It is the nature of science to consider divergent views and to select those most likely to achieve success. It is our hope that the 7th edition will continue to contribute to the success of that process.

The target audience of the 7th edition remains public health professionals, particularly those entering into the field, who wish to learn about the scope and diversity of the field and strategies to improve the health of the public. The ultimate goal of the 7th edition is to convey the

excitement and the power of public health to promote ‘health for all’! (Chapter 3.3).

Free personal online access for five years

Individual purchasers of this book are also entitled to free personal access to the online edition for 5 years via oxfordmedicine/otglobalpublichealth7. Please refer to the access token for instructions on token redemption and access.

Accessing this content online allows you to print, save, cite, email, and share content; download high-resolution figures as PowerPoint® slides; save often-used books, chapters, or searches; annotate; and quickly jump to other chapters or related material on a mobile-optimized platform.

During the production of this publication, new public health challenges were presented in the form of COVID-19. This has been addressed where possible in related chapters, but for a full chapter on the topic, please access the online version of this book at Oxford Medicine Online (oxfordmedicine/otglobalpublichealth7).

Preface to Volume 1: *The scope of public health*

This opening volume of the *Oxford Textbook of Global Public Health* showcases the breadth of public health in terms of the range of topics that are covered and the number of disciplines on which public health now draws. The scope of public health has continued to evolve and a strong public health base will be a key to meeting the United Nations' Sustainable Development Goals that relate to both the need for health improvement and for a reduction in inequalities in health. The contributions in this volume provide an introduction to the development of public health as a discipline in countries at different stages of development and give a detailed overview of areas of critical importance. It does this through three sections updated from the previous edition: the development of the discipline of public health, determinants of health and disease, and public health policies, law, and ethics.

Section 1 begins by considering the scope and concerns of public health in the twenty-first century, including an overview of many of the challenges facing contemporary public health, many of which are related to poverty. The next two chapters cover the history and development of public health in developed countries and in low- and middle-income countries. Chapter 1.4 then describes the development of public health in transition, focusing on middle-income countries. The section concludes with an account of how the increased interconnectedness of human societies, or globalization, is impacting on global public health both positively and negatively. This chapter discusses the shift in global health governance from international to global collective action and attempts to address the impacts of globalization through regulatory frameworks.

Section 2 provides in-depth coverage of the determinants of health and disease. A solid understanding of these determinants is necessary before any response to disease can be formulated and public health put into practice. The first chapter in this section presents an overview of biological,

behavioural, social, and environmental determinants of health, but gives particular emphasis to the social determinants of health because of their role in creating health inequalities. Governments (at all levels) have a role in the improvement of population health and the reduction of health inequalities through the creation of healthy public policy. This leads into a chapter on the politics of public health, new to this edition, which describes how politics sit alongside evidence in the formulation of policy. An evaluation of how the role of politics influences the adoption of public health policy is dependent on defining the problem and evidence, understanding the roles and players, understanding motivations, and understanding strategies and tactics. The authors use a number of case studies illustrating the interaction of evidence and politics including reproductive health rights for women in the United States. Chapter 2.3 then covers poverty, justice, and health, discussing the relationship between poverty and health and how there is often reference to human rights in justice theories that argue for the need to reduce or eliminate poverty to promote health. If we are to create a fairer society, public policy needs to be based on both equality of opportunity and equality of outcome. The following chapters discuss the determinants of socioeconomic inequalities in health in high-income and developing countries and what is known about how best to reduce them. Socioeconomic inequalities have been well described in high-income countries for a range of indicators of socioeconomic position and different health outcomes. We know much less about how to reduce health inequalities, and although a number of policies and interventions have been identified as having the potential to reduce inequalities, making progress in the reduction of health inequalities is dependent on international cooperation. In low- and middle-income countries, socioeconomic inequalities are often associated with high poverty levels but, despite the magnitude of such inequalities, there are few examples of the reduction of health inequalities becoming key targets of public policy. Agenda 2030 and the Sustainable Development Goals provide a useful multisectoral approach to address both health problems and their social determinants, and as such show a potential route to the reduction in health inequalities in low- and middle-income countries. Chapter 2.6 considers the advances that have been made in genomics and the opportunities and challenges that these present for public health. These include pharmacogenomics testing—

examining the effects that a person's genes have on their response to treatment by drugs—and the use of epigenetic therapy.

The following three chapters are devoted to long-standing public health concerns which remain central to the practice of public health: water and sanitation, food and nutrition, and climate change and human health. The lack of clean and safe drinking water and of basic sanitation and the diseases caused by these deficiencies are largely problems of low- and middle-income countries, and Chapter 2.7 details the major diseases and their aetiologies and considers interventions to prevent these. The following chapter provides an overview of the important role played by food systems and the need for cross-sectoral approaches to address undernutrition and overnutrition. This double burden of malnutrition has a common cause: a lack of access to affordable, quality sufficient foods, and examples are given from high-income and low- and middle-income countries of programmes attempting to address overnutrition and undernutrition, respectively. The main effects of climate change on health will be through the exacerbation of disease and injury from familiar causes. Since the populations that are most likely to be seriously affected by climate change are those that already face high burdens of disease it is important to improve baseline health in preparation. The overall response required will involve both coping with the health impacts of changes to weather patterns while halting emissions and considering ways to reduce existing pollutants in the atmosphere. The next chapter covers behaviours, the determinants of behaviours, and the many ways in which behaviours can influence health. Given that the environment can constrain or influence health-related behaviour, there is a clear need to develop interventions that target such environmental aspects. The final chapter in section two looks at the ways in which access to healthcare affects population health, covering issues including the roles of health policy, financing, and workforce planning.

The final section in this volume turns to public health policies, law, and ethics. The first chapter in this section looks at leadership in public health. Chapter 3.2 details how public health ethics originated, the issues that distinguish ethics for public health from other disciplines, and the ethical issues raised by genetic research. The following chapter considers the right to health and how this aligns with the goals of public health globally. The authors provide examples and case studies illustrating how human rights support global public health. Chapter 3.4, on law and the public's health,

considers the difficulty of balancing the promotion of health and protection of the population against individual liberties. Clearly there is a real need for global governance to combat disease and its vectors, and this means stepping beyond the health sector to encompass other areas affecting health including trade, food, migration, and the environment. The final two chapters of this volume cover health policy in developing and developed countries respectively. The focus of health policy varies between settings, but increased globalization leads to some commonalities between high-income countries and low- and middle-income countries. The reader is furnished with recommended strategies to strengthen health policy in developing countries along with examples of the failure of policy in developed countries.

In summary this volume details how broad the scope of public health has become as the twenty-first century develops. The contributors to this volume have been drawn from a range of disciplines and are all specialists in their fields. A common theme throughout is the need for the public health workforce to work collectively, across all disciplines, sectors, and countries, in the struggle to overcome emerging challenges and to improve global public health and reduce health inequalities.

AL

Preface to Volume 2: *The methods of public health*

Volume 2 of the seventh edition of the *Oxford Textbook of Public Health* presents the methods which bring scientific rigour to the public health endeavour. With a firm and broad grounding in the methods of public health, students and practitioners will ensure that their research and practice is based on robust evidence a critically important consideration in informing decision-making. The methodology utilized is a key for assuring the strength and validity of evidence for decision-making. Randomized controlled trials, systematic reviews, meta-analyses, and economic evaluations are accepted methods for providing clinical evidence but there are difficulties in applying these in a public health context where there are large target populations and long timescales for the emergence of outcomes. While evidence emanating from the application of these techniques has become more common to inform public health decision-making, there is increasing appreciation of the complexity of public health interventions and the need to use a range of disciplinary approaches to develop and evaluate these.

The range and complexity of health problems facing populations is also increasing, and public health methodologies must evolve and expand to meet this challenge and ensure effective responses. With globalization of emerging and re-emerging infections, and demographic, nutrition, and physical activity transitions, the methods of public health must be adapted to meet the new challenges. Since the sixth edition, the effects of globalization on health including the increasing importance of global environmental changes and notably climate change, have burgeoned. These new challenges are more difficult to study than the traditional concerns of infectious and non-infectious diseases and local environmental issues. The adaptation of old methods and the development of new ones are key to ensure the continued relevance and robustness of public health research. Public health practitioners have always had to face the dilemma of

balancing delays in action emanating from concern for methodological rigour with the need to act expeditiously. This dilemma is becoming increasingly complex and challenging as some of the new and emerging public health challenges are less amenable to traditional public health approaches and in some instances, are associated with ethical considerations that add to the complexity of the issue.

All the chapters in Volume 2 have been extensively revised and updated, and several new chapters added. This volume is organized into four sections: information systems and sources of intelligence; epidemiological and biostatistical approaches; social science techniques and environmental and occupational health sciences. Information systems are the foundation of all public health research and action. The lack of good information is still a barrier to effective action in much of the world. Basic information on births and deaths is not routinely available for most low-income and many middle-income countries. This gap remains a major impediment to tracking progress towards the Sustainable Development Goals. Fortunately, a concerted effort is now being made to close the gap, especially for maternal and child statistics with the support of several philanthropic foundations. Three chapters in this section (Chapters 4.1–4.3) examine the contrasting challenges facing information systems in both high-income and low- and middle-income countries. Chapter 4.2 by Zunyou Wu and Jennifer McGoogan captures the substantial advances being made in information systems and community diagnosis in low- and middle-income countries. Chapter 4.3 by Patrick Sullivan provides an insightful and contemporary overview of the impact of, and rapidly evolving new communication streams on public health.

Epidemiology and biostatistics are the core sciences of public health. Public health practice requires a firm connection to the priority health needs of populations. Epidemiological research is almost always required to establish this connection, and exceptions are few; some major acute outbreaks or overwhelming catastrophes do not allow for serious epidemiological investigation before the response is required. However, epidemiological study is still needed to assess the scope of the problem and the effectiveness of the response. Public health methods to ensure the appropriateness of inferences (Chapter 5.13) drawn from public health investigations—perhaps the most difficult and certainly the most contentious aspect of public health science—continue to evolve. This

process often requires a systematic approach to ensuring that all data from all studies—published and unpublished—are synthesized into a useable summary assessment (Chapter 5.14). A critical and expanding methodological area deals with interventions and their effectiveness at a community level by Kathy Baisley et al. (Chapter 5.8). Technological advances—computers and the internet—are changing the scope of public health and opening new possibilities, from data collection and analysis for the early identification of disease outbreaks to the use of modelling of disease transmission to predict the future trends and needs (Chapters 5.3 and 5.17). The methods and special issues facing clinical epidemiology are discussed in Chapter 5.10. The final chapter in this section stresses the essential importance of surveillance to monitor public health problems and the effectiveness of intervention programmes (Chapter 5.18). A new chapter in this section on qualitative research (Chapter 5.6) by Jennie Popay and Fran Baum covers both methodological approach and underscores the importance of understanding the voices of potential beneficiaries and Indigenous knowledge systems in the knowledge generation process.

Increasingly a more systems-based approach is being utilized to understand disease and risk. Rona Campbell provides an excellent update on new developments in the implementation of multicomponent interventions (Chapter 6.5). The completion of the human genome project is increasingly being translated to novel approaches to diseases including the use of gene therapy and leading to precision public health approaches. Of note are two new contemporary chapters in this section: Lifecourse epidemiology and analysis (Elizabeth Rose Mayeda) and Natural and quasi-experiments by Peter Craig (Chapter 5.10). The methodologies for measuring burden of disease Chapter 5.17 are particularly important as the implementation of these new methodologies is being used to provide the basis for both global and local rationing of resources and priority setting.

Social science techniques are assuming even greater importance to the practice of public health with the recognition that epidemiological information alone is not sufficient for the development and implementation of effective public health policies and programmes (Chapter 6.1). Demography is another underappreciated basic science of public health; the ageing of all populations, especially in low- and middle-income countries, will be a critical public health issue for the economic survival of these countries in the twenty-first century (Chapter 6.3). Health economics and

the use of cost-effectiveness analysis (Chapter 6.6) have expanded the audience for public health research to sectors outside health, especially the finance and development sectors, nationally and globally. Health promotion expands the focus of public health from a primary concern with disease prevention and control towards an understanding of the underlying determinants of health (Chapter 6.4). These and other social science tools, including management of the health programmes (Chapter 6.8), are key for the development and implementation of effective public health policy in all countries eloquently and comprehensively covered by Wafaa el Sadr and colleagues in a new chapter on Implementation Science and translational public health (Chapter 6.9). The HIV pandemic has brought renewed interest and focus on sexuality and health that Parker et al. cover eloquently in Chapter 6.2. A novel and increasingly used approach to programme and treatment adherence is incentivizing and supporting desired behaviours which is captured in the chapter on Behavioural Economics and Health (Chapter 6.7) by Harsha Thirumurthy et al.

Environmental and occupational health sciences cover traditional public health issues, as well as the even more difficult global health challenges that are discussed in Volume 1. This section deals with both traditional and emerging environmental and occupational health hazards, many of which have been exacerbated by globalization. (Chapters 7.1–7.3). The increasingly important issues of risk assessment and management, and risk perception and communication are covered in Chapters 7.4 and 7.5. The chapter on urbanization and health by Jason Coburn highlights how increasing urbanization is impacting public health.

The importance of methodological advances in public health is illustrated by the way in which many chapters in other volumes of this Textbook consider methodological issues in considerable detail—for example, the chapters on measuring the global burden of diseases and responding to global environmental challenges. The chapters in this section illustrate the evolution and breadth of public health methods as its scope continues to expand. No doubt, this process will continue well into the future and remains a good marker of the growth and evolution of the public health sciences as sound and rigorous strategies to address emerging and ongoing public health challenges.

QAK

Preface to Volume 3: *The practice of public health*

> *Public health is what we, as a society, do collectively to assure the conditions for people to be healthy. This requires that continuing and emerging threats to the health of the public be successfully countered … through effective, organised and sustained efforts led by the public sector. Institute of Medicine (1988)*[1]

The practice of public health has never been more vital. The social, economic, political, and environment threats to human health are accumulating in the twenty-first century. Volume 3 of the *Oxford Textbook of Global Public Health* provides an up-to-date account of how the practice of public health can contribute to reducing these threats through 49 chapters, each written by leading experts. The contents of this volume identify public health as a subject of local, national, and global concern, and a key responsibility of governments and public agencies, with the need to regular private industry in order to promote the health of the public more pressing. The chapters in this volume concern the practice of public health. They demonstrate the broad focus of public health and how more than ever public health is a global concern and requires effective global, national, regional, and local governance to ensure that life expectancy continues to increase and the reversals in life expectancy seen in some countries is reversed. This volume focuses on the application of population science methods to the major challenges being addressed through public health interventions and approaches. The chapters in this edition provide the evidence for public health's strategies, reassess priorities when required, recognize the evolving burden of disease and context in which they occur, and recommend new strategies for intervention.

Volume 3 begins with a discussion of the major groups of non-communicable disorders, including cardiovascular and respiratory diseases and cancer (Section 8). This section includes separate chapters on obesity, physical inactivity, and diabetes, reflecting growing concern at the increasing prevalence and growing impact of these conditions on global health. The chapter on obesity contains a crucial discussion on the

commercial determinants of health showing very clearly how marketing and free trade have made unhealthy high fat and sugar foods and beverages more accessible. Section 8 continues with a series of chapters on communicable diseases, with chapters on tuberculosis, malaria, hepatitis, and emerging and re-emerging infections and the threat of bioterrorism. Together these conditions represent major priorities: tuberculosis has been the cause of death for billion people since the 1900s and there were 6.3 million newly notified cases of tuberculosis (TB) worldwide in 2016; malaria accounts for nearly half a million death annually and the earlier success in reducing this number has stalled since 2015; while 328 million people are chronically infected with hepatitis viruses B and C, with one million deaths annually. As well as outlining problems and their causes, each of these chapters discusses potential solutions, including national and international strategies for disease control and prevention. Without significant process in each disease area the Sustainable Development Goals for 2030 set by the United Nations will not be achievable.

The emphasis on intervention for prevention of disease and promotion of health is continued in the volume's second section (Section 9) on public health hazards including tobacco, alcohol, drug abuse, injuries and violence Proposed intervention strategies encompass both population-based approaches; including, for example, regulation, the use of deterrents and incentives, and public education; and strategies targeted at individuals at high risk through healthcare services. It remains clear, however, that the greatest risks are generally found among those groups for whom interventions and environments conducive to good health are least accessible.

Section 10 considers the public health needs of different population groups paying particular attention to groups that for a range of reasons are vulnerable to public health hazards, disease risks, and increasingly emphasized in this revision is the inequitable impact of climate change on health status. Separate chapters outline the needs of families, women, children, adolescents, older people, ethnic minorities, people with disabilities, and forced migrants and displaced populations. While significant progress has been made in preventing child deaths, a staggering 5.4 million under 5-year-olds died in 2017. The largest ever cohort of adolescents now exists and their health and well-being is increasingly shaped by the global forces of urbanization, migration, global

communications, economic development, and the sustainability of planetary ecosystems. The chapter on people with disabilities notes that 15% of the world's population has a disability and that public health must frame responses within a social determinants framework to tackle underlying issues such as poverty and unemployment. The chapters on Indigenous peoples and prisons and public health similarly stress the importance of social determinants and demonstrate that the impacts of European colonization reverberate across the centuries and have causes multiple health issues for Indigenous populations worldwide. Chapter 10.7 notes that as the world faces the health issues of globalization and climate change, Indigenous knowledges and ways of being may offer important insights into managing these challenges. Collectively, these chapters emphasize the importance of the public health role in analysing the health needs of these often marginalized populations and advocating for their right to health and the living conditions that create health. Together the chapters provide clear directions on how to reduce health inequities within and between countries.

Section 11 presents an analysis of the core public health skills required for improving population health and reducing inequalities in health. This section begins with a chapter on the concept of need, which shows that technical assessments of the capacity to benefit from health intervention can rarely be separated from underlying assumptions concerning the justification and rationale for societal intervention. Action between and across sectors is usually vital and this is exemplified by chapters on current strategies for control of non-communicable diseases and infectious diseases. The chapter on the political economy of non-communicable disease also demonstrates the political nature of public health and the importance for public health practitioners to understand the implications of this for their practice. A series of chapters then outlines opportunities for intervention through the health sector including healthcare services, population screening, and environmental health practice. The section on the public health workforce includes chapters on training of community health workers, and public health professionals, to meet public health needs. There are also chapters on planning and responding to public health emergencies, including chemical and radiological emergencies.

In the final section of the book, Quarraisha Abdool Karim and Roger Detels question the assumption that intervention on public health problems must be led by the public sector. They describe an enhanced role for

powerful private sector advocates of public health intervention, while at the same time drawing attention to some of the challenges of this approach and the importance of the stewardship and governance role of governments. The closing chapter, by Tedros Adhanom Ghebreyesus (Director General of the World Health Organization), comments on several key issues that have been raised in earlier chapters of the book, analysing the pressing challenges now facing the public health community globally, and emphasizing that public health is a powerful driver for positive change to dramatically improve the health and lives of all people. In particular he notes how air pollution has become an even more crucial issue and requires a cross-sectoral response. He notes that the World Health Organization (WHO) expects approximately 250,000 additional deaths per year between 2030 and 2050 to be attributed to the health effects of climate change.

This volume shows the dynamic nature of the changing world in which we live and how old and new threats to health and well-being interact to challenge public health to respond creatively.

PDNA	post-disaster needs assessments
PEPFAR	President’s Emergency Plan for AIDS Relief
PF	prevented fraction
PHAC	Public Health Agency of Canada
PHCA	primary oral healthcare approach
PHE	Public Health England
PHEIC	Public Health Emergency of International Concern
PHM	People’s Health Movement
PHN	public health nutrition
PHR	public health research
PI	protease inhibitor
PIVOT	Prostate Cancer Intervention Versus Observation Trial
PM	particulate matter
PMI	President’s Malaria Initiative
PMTCT	prevention of mother-to-child transmission
POC	Point-of-care
POR	prevalence odds ratios
PPE	personal protective equipment
PPROM	Preterm premature rupture of membranes
PPV	pneumococcal polysaccharide vaccines
PPV	positive predictive value
PreP	pre-exposure prophylaxis
PRIO	Peace Research Institute in Oslo
PRISMA	Preferred Reporting Items for Systematic Reviews and Meta-Analyses
ProMED	Programme for Monitoring Emerging Diseases
PSA	prostate-specific antigen
PSBI	possible serious bacterial infections
PSHE	personal, social, and health education
PTSD	post-traumatic stress disorder
PURE	Prospective Urban Rural Epidemiology
PVP	predictive value positive
PWID	people who inject drugs
PYD	positive youth development
QALY	quality-adjusted life year
QIF	Quality Implementation Framework
QUAC	Quaker Upper Arm Circumference
QUADAS	Quality Assessment of Diagnostic Accuracy Studies
R&D	research and development

RA	rheumatoid arthritis
RCS	respirable crystalline silica
RCT	randomized controlled trial
RCV	rubella-containing vaccines
RD	regression discontinuity
RDD	random digit dialling
REACH	Registration, Evaluation, Authorisation, and Restriction of Chemicals
REACT	Randomised Evaluations of Accepted Choices in Treatment
REP	Rochester Epidemiology Project
RHIS	routine health information system
ROC	receiver operator characteristic
ROI	return on investment
RP	restorative practice
RPA	rapid participatory appraisal
RR	rate ratio
RR	relative risk
RSV	respiratory syncytial virus
RT	reverse transcriptase
RTW	return to work
RVF	Rift Valley fever
SAHNA	South Asian Health Needs Assessment
SAM	severe acute malnutrition
SAR	structure activity relationship
SARI	severe acute respiratory infection
SCC	squamous cell carcinoma
SCD	sickle cell disease
SCIH	Swiss Centre for International Health
SD	standard deviation
SDC	Swiss Agency for Development and Cooperation
SDG	sustainable development goal
SDH	social determinants of health
SDIL	Soft Drinks Industry levy
SDOH	social determinants of health
SE	standard error
SES	socioeconomic status
SEYLE	Saving and Empowering Young Lives in Europe
SF	spotted fever
SG	standard gamble
SHS	second-hand smoke
SIS	Statistical Information System
SIV	simian immunodeficiency virus
SMA	spinal muscle atrophy
SMART	Sequential multiple assignment randomized implementation trial
SMD	standardized mean difference
SMR	standardized mortality ratio

SNP	single nucleotide polymorphism
SPRINT	Systolic Blood Pressure Intervention Trial
SRH	sexual and reproductive health
SRNT	Society for Research on Nicotine and Tobacco
SSB	sugar-sweetened beverage
STEM	science, technology, engineering, and mathematics
STH	soil-transmitted helminth
STI	sexually transmitted infections
SUD	substance use disorders
SUDEP	sudden unexplained death in people with epilepsy
SUDI	sudden unexpected death in infancy
SUN	scaling up nutrition
TALENS	transcription activator-like effector nucleases
TasP	Treatment as Prevention
TBA	traditional birth attendant
TBI	traumatic brain injury
TCV	typhoid conjugate vaccine
TDF	tenofovir disoproxil fumarate
TDF	Theoretical Domains Framework
TEDS	Treatment Episode Data Set
TFR	total fertility rate
THS	third-hand smoke
TIA	transient ischaemic attack
TIPS	Treatment and Identification of Psychosis Study
TLV	threshold limit values
TNT	Treat to New Targets
TPFR	total period fertility rate
TST	Tuberculin skin test
TTCV	tetanus-toxoid-containing vaccines
TTO	time trade-off
TTP	trusted third party
TTS	temporary threshold shift
UAV	unmanned aerial vehicles
UDHR	Universal Declaration of Human Rights
UHC	universal health coverage
UIS	UNESCO Institute for Statistics
UK	United Kingdom
UKPDS	United Kingdom Prospective Diabetes Study
UMV	unmanned maritime vehicles
UN	United Nations
UNCRC	United Nations Convention on the Rights of the Child
UNGA	UN General Assembly
UNHCR	United Nations High Commissioner for Refugees
UNICEF	United Nations Children’s Fund
UNISDR	United Nations International Strategy for Disaster Reduction

UNMEER	UN Mission for Ebola Emergency Response
UNOCHA	United Nations Office for Coordination of Humanitarian Affairs
UNODC	United Nations Office on Drugs and Crime
UR	uncertainty range
US	United States
USAID	United States Agency for International Development
USCRI	US Committee for Refugees and Immigrants
USD	United States dollars
USDA	US Department of Agriculture
VA	verbal autopsy
VADT	Veterans Affairs Diabetes Trial
VAS	visual analogue scales
VAW	violence against women
VFD	Veterinary Feed Directive
VGDF	vapours, gases, dusts, and fumes
VIP	ventilated improved pit
VLGA	Victorian Local Governance Association
VR	vital registry
VZV	varicella zoster virus
WEA	work-exacerbated asthma
WFP	World Food Programme
WFS	World Fertility Survey
WGS	whole genome sequencing
WHA	World Health Assembly
WHAS	Worcester Heart Attack Study
WHO	World Health Organization
WRA	work-related asthma
WRMSD	work-related musculoskeletal disorders
WRSD	work-related skin diseases
WSP	Water and Sanitation Programme
WTCCC	Wellcome Trust Case Control Consortium
WTO	World Trade Organization
YLD	years lived with disability
YPLL	years of productive life lost
YSP	Youth Smoking Prevention
ZFN	zinc fingers nucleases

Zwi** Professor of Global Health and Development, School of Social Sciences, University of New South Wales, Australia

The SARS-CoV-2 Pandemic

Quarraisha Abdool Karim, Fran Baum, and Roger Detels

Summary

The SARS-CoV-2 pandemic is the most recent and challenging pandemic facing humanity in the twenty-first century. While it is a reminder of our global interconnectedness and shared vulnerabilities, it has also highlighted the stark inequities within and between countries that render some more vulnerable than others. The disruptions to the economy and loss of lives unmasked yet again the intersection of race, gender, displacement, and poverty as well as the differing vulnerabilities of those who could not pivot to remote working, access health services, ensure food and income security, or implement public health measures, and those who could.

In the words of António Guterres, United Nations Secretary-General at the 2021 High Level Political Meeting on Accelerating progress on the 2030 Sustainable Development Goals (SDGs):

> *This crisis is a wake-up call to do things differently. We need a recovery based on economic and social justice since response gaps in pandemics, whether HIV or COVID-19, lie along the fault lines of inequality.*

Country responses to this pandemic, identified in early 2020, provide important insights on political leadership and commitment in the face of an emergent crisis and balancing or prioritizing saving lives, livelihoods, and interrupting chains of viral transmission. The returns on investments in epidemic preparedness including modernized health information systems, access to healthcare, critical care capacity, investments in science and technology, and/or bulk manufacturing and distribution capacity enabled some countries to respond more rapidly. Trust in government continues to influence individual-level decisions on the adoption of public health and

social measures. The rate of knowledge generation has been unprecedented, for example, the identification of the causative organism within weeks; the development of diagnostic assays; development of six highly efficacious vaccines in 2020; and the importance of oxygen and dexamethasone for survival in the face of severe disease. Many political leaders have had their responses guided by the science despite substantial scientific uncertainty. Others have ignored scientific advice causing their countries to suffer rapid transmission, rampant infections, and death overwhelming their healthcare systems. This ongoing pandemic provides opportunities to reflect on the strengths and weaknesses of global and country responses to SARS-CoV-2 and the need to respond to multiple parallel pandemics. The hope emanating from vaccines informed by mimicking natural recovery from infection has been dampened by inequitable access as a result of vaccine nationalism. The ongoing emergence of new variants of concern of SARS-CoV-2, even in the face of high vaccine coverage rates in some countries, highlights the need to better understand viral immune escape and redefine what epidemic control needs to look like. At the time of writing (August 2021) it is evident from the emergence of the Delta variant, the most transmissible variant of concern, that the pandemic is far from over. The reluctance of many to accept vaccination; the third and fourth waves/surges of infections in mid-2021; the growing cohorts of long COVID-19 patients are sobering reminders of how little we know about SARS-CoV-2 and COVID-19, and how uncertain the future is in terms of when countries can safely implement their post-COVID-19 social and economic recovery plans. This chapter highlights key elements of the biology of SARS-CoV-2 infection; effective responses to SARS-CoV-2; the interaction between SARS-CoV-2 and HIV; and the opportunity and importance of control of existing non-communicable diseases and other serious communicable diseases in the face of the pandemic. It illustrates the application of basic and more advanced epidemiological concepts of pandemics; public health responses; communication strategies, case identification, isolation, and quarantine; incidence and prevalence; principles of screening in use of diagnostic assays; herd immunity; transmission dynamics; molecular surveillance and use of genomics and meta-data. The pandemic underscores the challenges of responding effectively to global emergencies and disasters and the need for solid investments in epidemic and pandemic preparedness. SARS-CoV-2 provides an opportunity to rethink global health, the importance of

partnerships and collaborations between countries and between governments and the public; revisiting intellectual property rights in relation to the public good in the context of global emergencies and disasters; and opportunities for accelerating progress on the UN 2030 Sustainable Development Goals through addressing the root causes of inequalities.

1. The emergence of a new pandemic

On 27 December 2019, a physician in Wuhan, China reported seeing an unusual pneumonia to the Jiangshan District Center for Disease Control. Within four days an epidemiologic alert had been raised by the local health authority, and the Chinese Center for Disease Control initiated an investigation. Initially suspicion involved a seafood market as the source of cases and the Huanan Seafood Market in Wuhan was closed down immediately. But by then, secondary cases without a history of contact with the market were already occurring. By 3 January 2020, China notified the World Health Organization (WHO) and other countries that an epidemic of an unknown disease was occurring in the Wuhan area (1). By 7 January 2020, a corona virus, named by WHO, the severe acute respiratory coronavirus 2 (SARS-CoV-2), was identified as the cause of the corona virus disease 2019 syndrome (COVID-19) (2). Remarkably, within three days the genetic sequence of the virus was elucidated and shared with WHO and, through open-source access, facilitated the development within days of a diagnostic polymerase chain reaction test in Germany to identify infected individuals (3).

By 17 January 2020, most countries had started to implement some form of port of entry (thermal and/or symptom) screening for COVID-19. By 21 January and 24 January 2020, the first cases were reported in the United States and Europe, respectively. On 20 January 2020, COVID-19 was added to the WHO list of notifiable diseases and three days later, on 23 January 2020, Wuhan was placed on lockdown, cases isolated, and contacts quarantined. On 30 January 2020, WHO declared the SARS-CoV-2 pandemic a Public Health Emergency of International Concern that was followed by similar national declarations in several countries around the world (4).

The early action by the government of China successfully slowed the spread of SARS-CoV-2 in China but at the cost of limiting civil liberties

through rapidly enforced isolation of cases, quarantine of contacts, and forceful implementation of 'lockdown' regulations. These important milestones and timelines are captured in Figure 1.

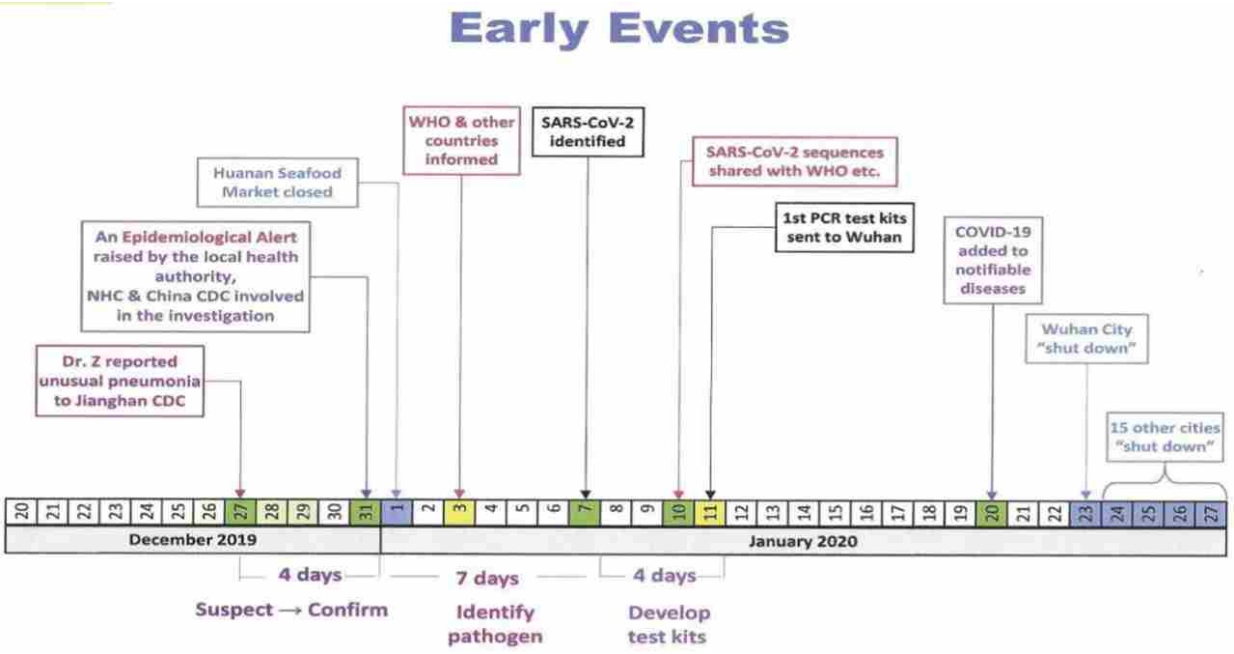

Figure 1 Timeline for the emergence of a new pandemic in China and key milestones.

2. The first 18 months of the pandemic

As the virus started to spread beyond China, countries started to implement national programmes to respond to the emerging epidemics within their countries, some guided by the Chinese government response. There were wide variations in responses that were influenced by, among others: political leadership; public fear and anxiety of the unknown; economic and human rights considerations that had implications for the epidemic trajectory within a country as well as for the global trajectory of SARS-CoV-2 infections (5). From mid-January 2020 to mid-March 2020, return from travel to countries with identified COVID-19 cases was viewed as the main risk factor for infection and diagnostic testing was restricted to symptomatic individuals who had recently returned from a country with COVID-19 and their close contacts. In contrast to China, Singapore, New Zealand, and South Korea,

most governments spent days and weeks debating issues like isolation, quarantine, banning or restricting large gatherings, criteria for eligibility for diagnostic testing; mandatory wearing of masks, social distancing, and lockdown regulations which, combined with a lack of national leadership, allowed the virus to spread largely unchecked within communities. Delays in the implementation of prevention strategies; lack of unity in action; poor preparedness of health facilities for hospitalization of severe cases; supply chain challenges for personal protective equipment; access to reliable diagnostic tests and/or reagents; capacity to identify, isolate, and quarantine cases contributed to the success or failure to contain the spread of the virus and the COVID-19 mortality rates at a country level. By April 2020 most countries had established special COVID-19 Science Advisory Groups or COVID-19 Task Forces, instituted declarations of COVID-19 as a public health emergency and introduced restrictions against large gatherings; school closures; curfews, and were implementing public health and social measures such as mask wearing; social distancing and isolation of confirmed cases. The goal of most country responses was to slow down the spread of SARS-CoV-2 and prepare health facilities to manage the care of severely ill COVID-19 patients.

The United States of America (USA), United Kingdom (UK), and Italy suffered among the highest incidence and mortality rates globally (6, 7). After an initial delay, the UK subsequently implemented strong responses and Neil Ferguson is quoted as saying ‘institution of a national lockdown one week earlier would have reduced the COVID-19 mortality rates by 50% in the UK’ (8). The anticipated high rates of COVID-19 in most low-and-middle-income countries (LMICs) did not unfold in the first half of 2020. Over the past 18 months we have seen the emergence of waves/surges of infections every 90–120 days with the most recent (fourth wave) occurring even in countries with high vaccination coverage rates. By early 2021, as the high death rates in the USA started to decline we saw substantial increases in cases in Brazil, India, and Indonesia. As of mid-August 2021, globally there were 207 million cases of COVID-19 and 4.3 million COVID-19-related deaths and most countries have been experiencing a new surge of infections (6, 7).

As the virus has continued to spread unrelentingly and with high speed in the past 18 months, our knowledge and understanding of this new pandemic

has grown in parallel and continues to grow as described by some as analogous to ‘building the ship while it is sailing’.

3. Biology of SARS-CoV-2

Coronaviruses are a very diverse family of enveloped, single-stranded ribonucleic acid (RNA) viruses (9, 10). Coronaviruses, first discovered in the 1960s, are found in birds and mammals, especially in bats, civets, camels, and rats. Coronaviruses constitute the subfamily *Orthocoronavirinae*, family *Coronaviridae*, and order *Nidovirales*, which is further subdivided into four genera (Alpha-, Beta-, Gamma-, and Delta-). SARS-CoV-2 is a beta-coronavirus (β-CoV) and is the seventh coronavirus known to infect humans. Notwithstanding restricted geospatial transmission, SARS-CoV-1 (Asia) in 2003 and MERS-CoV (Middle East) in 2012 caused serious disease. Coronaviruses HKU1, NL63, OC43, and 229E are associated with mild symptoms and represent about a fifth of ‘common colds’ in most parts of the world. SARS-CoV-1 caused a much smaller pandemic and ultimately has disappeared globally. MERS-CoV has caused localized epidemics in the eastern Mediterranean area, Korea, and Thailand and is still present in camels in the Middle East. MERS has a case fatality ratio of over 30%. Both SARS-CoV-1 and MERS are thought to have originated in bats, which are immunologically very permissive, and gone through an intermediate animal host—for SARS-CoV-1, civets and for MERS, camels. SARS-CoV-2 is thought to have undergone a similar process originating in bats but an intermediate animal host has not been identified (9, 10).

The inability to identify a likely animal intermediary host has resulted in considerable controversy about the origin of the virus, much of which involves international politics (11). The true origin of SARS-CoV-2 in humans remains to be established. Phylogenetic analysis (the study of evolutionary relationships among biological entities, often species, individuals, or genes, where viruses isolated from humans and or other animal species are sequenced and compared to identify common ancestry or where differences exist between species) suggests that bats are the most likely original host. Phylogenetic analyses show that the pangolin coronavirus is genetically related to the SARS-CoV-2 and other bat coronaviruses. It carries the same receptor binding domain as does SARS-

CoV-2 but the rest of the virus is only 90% genetically similar. Pangolins may therefore not be the intermediary host. SARS-CoV-2 binds with high affinity to human angiotensin-converting enzyme-2 (ACE-2) as its cellular receptor and uses it as an entry point to invade target cells in humans. ACE-2 receptor expression is much higher in the lower lobes of our lungs compared with the upper respiratory tracts (12).

SARS-CoV-2 has four structural proteins: spike (S), membrane (M), envelope (E), and nucleo-capsid (N) (9, 10). The spikes on the surface of SARS-CoV-2 virus particles each comprise three identical subunits, each of which, in turn, is made up of two functional components; the S_1 part is responsible for binding to the host cell receptor and the S_2 part is for the fusion of the viral and cellular membranes. The spike protein binds to the cellular ACE-2 receptor of the cell by which it gains entry into a cell through a process of fusion to the cell membrane and uncoating of the virus in the cytoplasm of the cell. Unlike retroviruses, the intracellular process of replication of coronavirus does not involve entry of viral material into the nucleus and genetic DNA of the host cell. Once in the cytoplasm of the cell the infecting virus is subject to a series of complex steps resulting in the expression and replication of messenger RNA and genomic RNA to produce full-length copies that are incorporated into the newly produced viral particles which are secreted and released by exocytosis.

Despite the RNA proofreading function of the virus, the high incidence of infections in humans provides opportunities for mutations in the SARS-CoV-2 virus genome and the development of variants (distinct viruses with a specific combination of mutations) that is discussed further in Section 10.3.

4. Transmission of SARS-CoV-2

Transmission in most instances takes place via inhalation or contact with mucosal surfaces of respiratory droplets (generated through coughing and sneezing) or the much smaller and lighter respiratory aerosols (generated by normal breathing, talking, or singing), and by direct transfer of virus particles from contaminated surfaces to the mouth, nose, or eyes (13). Airborne transmission is most likely to occur at short range, but longer-range transmission can occur in poorly ventilated spaces. Transmission also occurs through direct contact with still-active virus left on surfaces in the immediate

environment of, or on objects used by, actively infected persons. The stability of the virus in air and on various surfaces varies widely. For example, on copper it is 4 hours, 24 hours on cardboard, 48 hours on stainless steel, and 72 hours on plastic.

The virus is usually detectable in the nasopharynx/oropharynx 1–3 days before the onset of symptoms (13). The viral load peaks around the time of symptom onset. Viral loads are generally higher in sputum specimens than in nasopharyngeal or oro-pharyngeal swabs. The virus is detectable by PCR in the nasopharynx/oropharynx for ≥7 days after the onset of illness in most cases, but culturable virus appears to be rare after day 7. Pre-symptomatic transmission is an important contributor to community transmission, estimated to be up to 50%. Transmission occurs from symptomatic cases in the first few days of symptoms. Transmission after 7 days of illness is likely to be rare. The diagnostic test positivity rate is recommended by WHO as a proxy marker of transmission rates and test positivity rates of <5% is considered as a marker of low levels of transmission (14).

Two studies provided important insights on viral transmission very early on in the pandemic (15, 16). The first are data from a cruise ship, the Diamond Princess, that showed that for every 100 symptomatic cases, there were an additional 19 asymptomatic cases. The overall test positivity rate was 19% in the sample of the total population on the cruise ship. In contrast, data from the US aircraft carrier, Theodore Roosevelt, demonstrated that there could be as many as 120 asymptomatic cases for every 100 symptomatic cases. The test positivity rate was 15% in this cohort. An important confounder in the data from these two ships is age, with the Diamond Princess having many more older people in contrast to the younger cohort of military personnel on the Theodore Roosevelt.

Transmissibility can be described with the basic reproduction number (R_0), which was estimated at between 2 and 3 for the original Wuhan strain of SARS-CoV-2 (and is now estimated to be 6–8 for the Delta variant, highlighting the increased transmissibility of the Delta variant) (17). This can be contrasted to seasonal influenza with an R_0 around 1.3. R_0 simply expresses how many people on average will be infected by each patient, and it is calculated with the product of the probability of transmission, the number of contacts per unit time, and the duration of infectiousness (18). Thus, interventions aimed at reducing the rate of spread to less than 1 need to influence one or more of these variables. Typically for herd immunity to

be reached, R0 has to be <1, or in other words, each person infected is unlikely to spread infection to anyone else. To create a time-dependant reproductive number, a new approach was adopted called $R_{t.}$ $R_{t.}$ is important as it takes into account the lag between cases and provides a more accurate estimate of the quantity of viral spread. R_t cannot be measured but it can be estimated for any period of time, with 7 and 14 days being the time periods of interest for Sars-CoV-2 (19, 20). Further $R_{t,}$ takes into account vaccination coverage rates and adoption of other prevention measures.

The virus spreads easily and remains viable outside the body for several hours or days depending on the way it leaves and the material of any surfaces it lands on (13). Stopping spread is complicated as the virus is highly infectious and spreads even before an infected person has symptoms (pre-symptomatic spread) and, further, the majority of exposed and infected individuals remain asymptomatic. The transmission rate is high, on average one person infects between two and three others; but, in the circumstances in which spreading is most effective (closed, unventilated spaces with many people not wearing masks and talking or singing, etc.), superspreading can occur with tens or hundreds of people being infected in a single event (21). It is estimated that about 80% of transmissions take place at such superspreading events from less than 10% of infected individuals. Even when substantial reductions in new infections have been achieved, there can readily be a resurgence of infection. The virus replicates and spreads rapidly within a matter of days. This rapid spread and surge of infections can easily overwhelm health services and divert attention from other serious health problems, resulting in higher death rates (22). During winter it is challenging to differentiate between flu and COVID-19.

5. Temporal trends in SARS-CoV-2 infections and national responses

The global numbers of SARS-CoV-2 cases and COVID-19 deaths masks wide variations within and between countries in terms of magnitude of epidemics, severity of disease presentation and mortality rates (Figure 2) (6, 7). For example in Africa, while there have been 6.2 million cumulative cases representing 3.2% of global cases by mid-August 2021, it has a high case fatality rate of 2.5% (158,697 deaths) translating to approximately 3.8%

of global deaths in 15% of the world's population (6, 7). By the beginning of August 2021, most countries had experienced at least three surges or waves of infections with brief respites of between 90–120 days between surges. Some countries are now experiencing a fourth wave of new infections (6, 7).

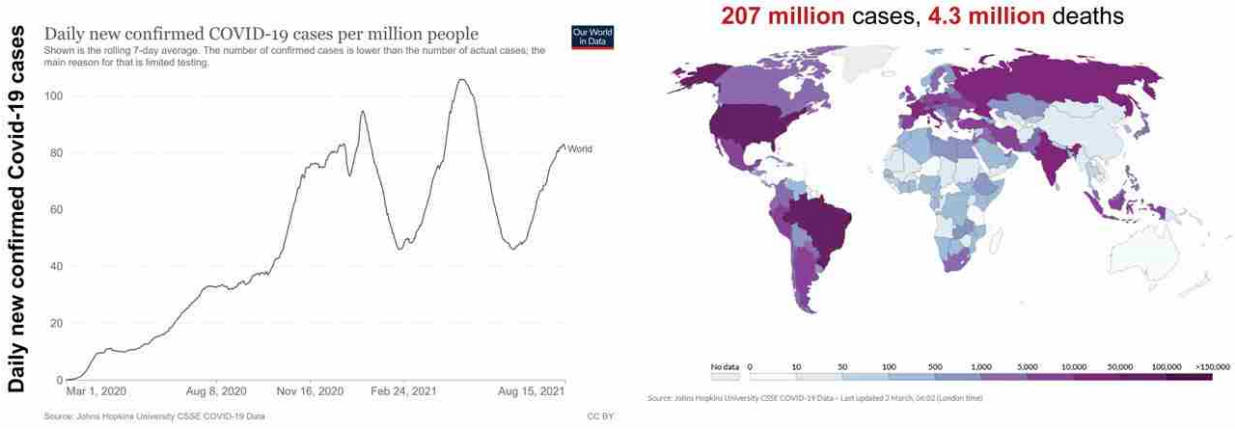

Figure 2 Temporal trends in global distribution of COVID-19 infections.

National responses to the pandemic have varied considerably and with the ongoing pandemic and waves of resurgences at a national level, continued to evolve in the first six months of the pandemic. Those countries, such as Australia, New Zealand, China, South Africa, and South Korea, that implemented strict national lockdown measures and closed ports of entry, were able to avoid widespread transmission whereas other countries, like the United States and Brazil, where limiting personal freedom was avoided on political grounds, experienced severe epidemics (23).

In September 2019, the Global Health Security Index (24) predicted that the world in general was not well prepared for the pandemic but did not predict individual country preparedness. In contrast to other pandemics and most diseases, in the first year of the SARS-CoV-2 pandemic rich countries suffered a higher burden of disease and death than most middle- and low-income countries (25). An analysis of the factors that appear to affect country epidemic trajectories and resilience indicates that the following factors were important:

The extent of globalization and geography: Most rich countries were more highly globalized and linked. Geography itself was a determinant such that island countries and those with only one border were more protected.
Health system capacity: Nations with universal publicly funded health systems that were not financially distressed and had strong public health capacity, appear to have been relatively well prepared for COVID-19, including Australia and New Zealand. Conversely, the pandemic highlighted the weaknesses of fragmented systems relying on for-profit healthcare providers, such as the USA.
Political leadership: Those countries with leaders who denied the scientific advice (including Brazil and the USA) fared badly. Others that acted on scientific advice fared better (e.g. South Africa, Australia, and New Zealand).
A country's wealth was not the only or main determinant of health security. Some lower-income countries made a conscious decision to allocate their scarce resources to prioritize their COVID-19 response including taking out loans to cover the increased debt resulting from the pandemic measures implemented (26, 27).
The extent of inequalities within countries also affected how well a country managed the pandemic. Those with high levels of inequities appear particularly vulnerable, as is discussed next.
Social security provisions to protect people from losing their jobs and homes was a vital part of pandemic responses (28)
An active civil society also played an important role in improving a country's pandemic responses. social solidarity built on civil society engagement offered protection even where trust in government was weak. For example, in South Africa, community action networks worked to both ameliorate the consequences of lockdown and reduce local transmission prevention (29). Using social media, they built local relationships based on trust and created a collective consciousness for responses to COVID-19 which has challenged divisive individualism.

6. Preventing the spread of SARS-CoV-2

Prior to the development of efficacious vaccines in November 2020, the only strategies effective in slowing the transmission of SARS-CoV-2 were the classical public health strategies of identification and isolation of cases and

quarantine of contacts. The collection of prevention measures to minimize the spread of SARS-COV-2, also sometimes referred to as the ‘COVID-19 prevention toolbox’ includes**:** symptom screening**;** staying home if symptomatic; hand sanitizing; regular cleaning of frequently touched surfaces and objects; use of face masks (cloth or medical masks) when interacting with others or in closed spaces; and maintaining social distance (>2 metres) (30). All healthcare workers need personal protective equipment (PPE), which includes combinations of respirators, surgical masks, face shields, goggles, gloves, plastic gowns or aprons depending on the risk of exposure in care provision.

Early in the pandemic, national lockdowns were an extreme form of social distancing used by some countries to slow down the spread of SARS-CoV-2 and utilize the time to prepare healthcare facilities to cope with the anticipated increase in patients with severe disease. Another form of social distancing adopted was remote working or schooling that was also referred to as voluntary ‘stay at home’ strategies. Restrictions on movement included policies against social gatherings including political rallies, sports events, and religious gatherings, entertainment venues, closing of shopping malls, and other circumstances or places in which people would come in close contact with others. In other situations where exposure to other people could not be avoided, especially in health facilities and other essential service points, masks and protective gear were strongly advised or mandated. The adoption of these prevention measures nationally or for individuals became a political issue; for example, in the United States of America the wearing of a mask was considered by many to be an expression of political affiliation (31). The implementation of any level of lockdown caused severe economic hardship, with many persons losing employment and many businesses closing down (32). In other settings, the enforcement of mandatory national lockdowns with curfews resulted in severe violations of human rights including loss of lives. Regardless of the measures adopted, the COVID-19 pandemic has resulted in the most severe economic and social disruptions and has resulted in societal divisions in many settings (33). Twenty months into this pandemic, implementation of national lockdowns is considered very parsimoniously by most governments and in fact the focus now is on striking a better balance between saving lives and livelihoods and living with the virus in our midst, implemented through varying degrees of restrictions based on magnitude of surges or declines of new infections. Notwithstanding

the public health rationale, we continue to see public protests, particularly in industrialized countries, when any form of lockdown measures are instituted.

The only way to identify someone who is infected is through viral diagnostic testing (21). The early development of diagnostic tests facilitated identification of cases. There are currently two types of diagnostic tests available for COVID-19 viral tests—polymerase chain reaction assays and rapid antigen tests. The timing of testing is critically important; testing too early after exposure or after the peak stage of infection, yields a negative test result (21) (Figure 3). The molecular real-time polymerase chain reaction (RT-PCR) test detects the virus's genetic material collected from respiratory specimens, such as nasopharyngeal, nasal, or oropharyngeal swabs, or sputum. False-positive results can occur with PCR tests, because non-viable genetic material may linger in the body long after recovery from an infection. False-negative results from antigen tests may range from 20 to 30%. Importantly, even in symptomatic individuals and their contacts a negative viral test only indicates that in that individual the virus is not detectable and repeat testing is necessary to accurately measure infection and contain further spread.

An antibody test confirms past infection and provides important individual or population level data of prior infection. It can take 1–3 weeks post-infection for detectable antibodies to emerge. Some serological assays differentiate between different classes of immunoglobulins with IgM detected earliest during infection followed by IgG. IgA is detectable at mucosal surfaces (26). Given that SARS-CoV-2 is a new virus, we are still learning about immune response and the durability of protection including vaccine-induced immunity. While it was initially thought that immunity from natural infection offered protection against re-infection for several months, the repeated waves/surges of infection and the emergence of variants of concern even in countries with high vaccination coverage rates indicate a more complex interplay between host immune responses and the evolution of viral immune escape. Anti-spike antibody tests are used to detect vaccine-induced immunity and are different from antibody tests used to detect natural infection.

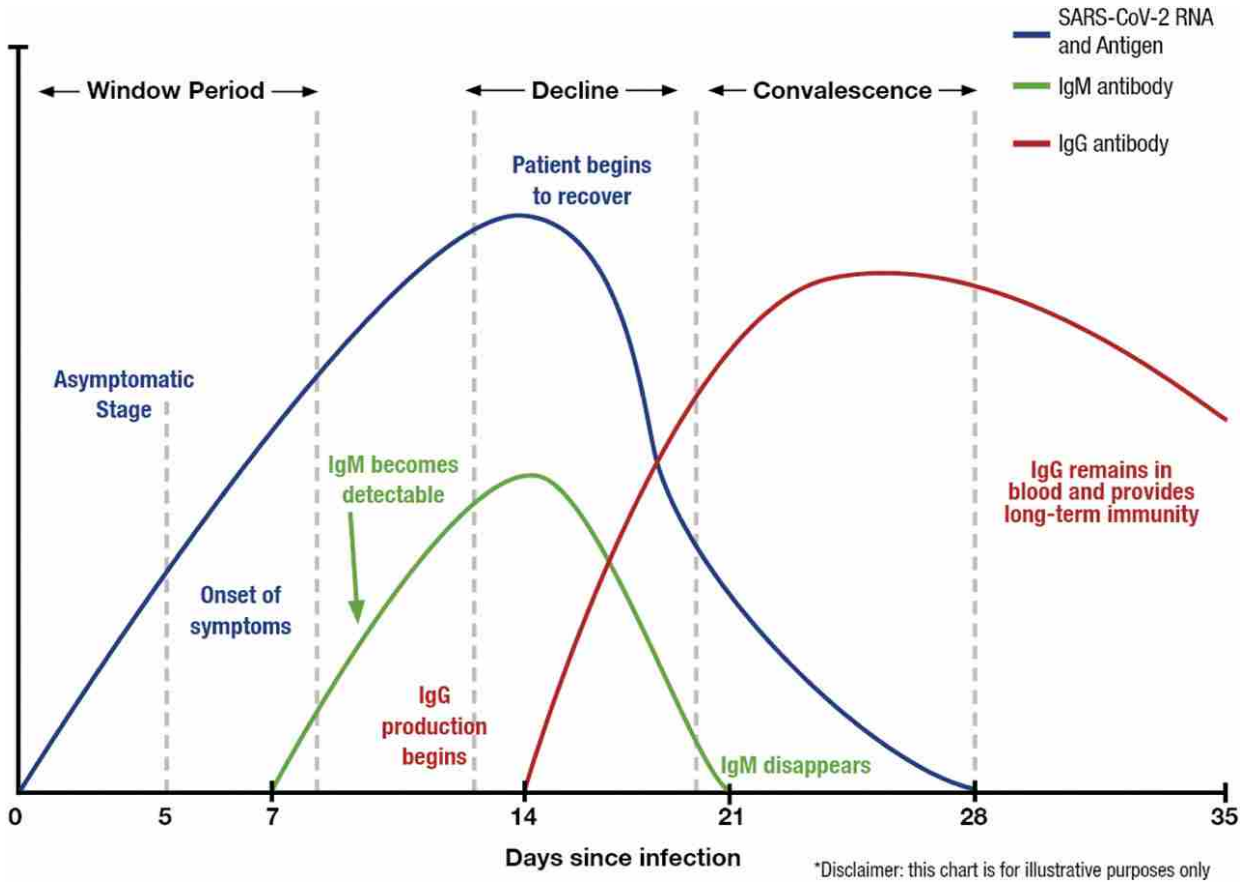

Figure 3 Detecting SARS-CoV-2 infection—viral and antibody kinetics.
Source: Senthuraman N, Jeremiah SS, Ryo A. Interpreting diagnostic tests for SARS-Cov-2. *JAMA* 2020, 323(22):2249–51.

Several factors contribute to the challenges of containment of SARS-CoV-2. These include:

Pre-symptomatic infectiousness where individuals unknowingly are spreading the virus prior to developing symptoms;
Asymptomatic infectiousness where individuals are unknowingly spreading the virus without ever knowing they have the infection;
Rapid spreaders/superspreaders where an infected person infects more than one other person or at events, such as large gatherings, where several hundred or thousand people can get infected from a few infected persons; for example, patient 31 in South Korea who through her social interactions infected over 1,000 people in a few days;
Repeated waves or resurgence of infections where after the initial epidemic is controlled a new surge of infections occurs creating an ever-present risk of new epidemics;
Emergence of new variants of concern that are able to escape natural or vaccine-induced immune responses.

Efforts to test both symptomatic and asymptomatic individuals through contact tracing and community testing in most countries were constrained by logistics, capacity, and delays in undertaking large numbers of RT-PCR tests; the need for repeated testing, the high cost of testing; supply chain issues and access to test kits due to global demand and travel/flight restrictions. In many settings, contact tracing had to be abandoned as diagnostic kits were correctly prioritized for confirmatory testing of hospitalized COVID-19 patients (34). The emergence of rapid, point-of-care diagnostic viral tests has assisted with rapid screening of large numbers of individuals leading to better surveillance and containment of viral spread in some settings. Measures of voluntary isolation of confirmed cases and a 10-day quarantine of potential contacts is commonly instituted to assist with viral containment efforts.

7. The natural history and disease progression of COVID-19

Infection with the SARS-CoV-2 results in a range of clinical manifestations ranging from asymptomatic infection to death. Figure 4 is a schematic representation of the natural history of COVID-19, from onset to recovery or death (35). There are basically three stages or phases in the natural history of COVID-19: the first phase is related to the onset of the disease and is generally characterized by the development of influenza-like symptoms from

mild to moderate. Some individuals recover and some progress to the second phase. Depending on the severity of phase 2, patients can improve or worsen with the necessity of intubation and mechanical ventilation. Phase 3 is characterized by hyperinflammation and sepsis of lungs. Patients with severe disease require treatment in an intensive care unit (ICU) and most of them, unfortunately, cannot overcome the infection and may eventually die.

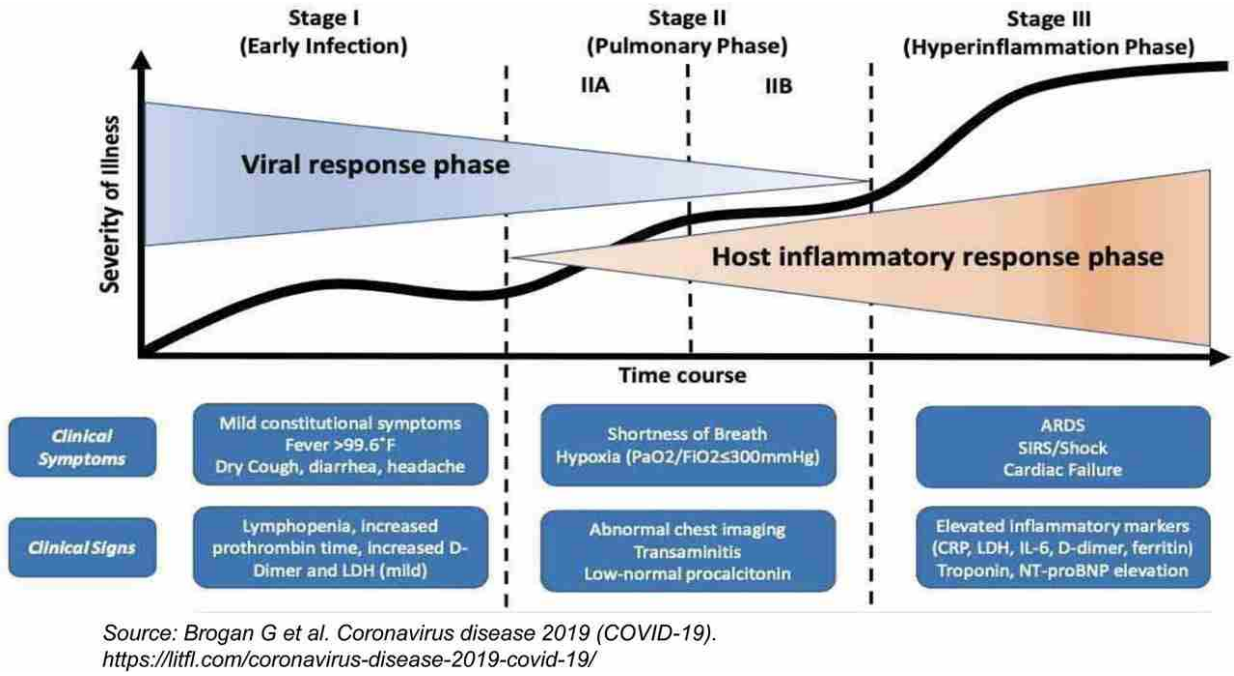

Figure 4 Natural history of COVID-19 infection.
Source: Brogan G et al. Coronavirus disease 2019 (COVID-19). https://litfl.com/coronavirus-disease-2019-covid-19/.

In the asymptomatic or pre-symptomatic stage, the individual has a positive nucleic acid amplification test but no symptoms consistent with SARS-CoV-2 infection. The individual may either resolve the infection or progress to a more serious stage of infection. An individual in the asymptomatic or pre-symptomatic stage can transmit the virus complicating surveillance and contact tracing. Some infected individuals progress to the mild stage, manifested by a range of symptoms including fever, cough, nausea, vomiting, malaise, headache, and diarrhoea and in some individuals loss of smell (anosmia) and/taste (ageusia) (Table 1) (36). Once the individual has developed shortness of breath, dyspnoea, and signs of lower

respiratory disease with an oxygen saturation level of 94% or higher, they are considered to be in the moderate stage of disease. Once their oxygen saturation level falls below 94% and they have a breathing frequency greater than 30 breaths per minute they are considered to have severe disease. In the critical stage patients progress to respiratory failure, septic shock, and death. The likelihood of serious disease is greater in individuals 65 years or older and those with underlying conditions including obesity, metabolic syndrome, type 2 diabetes, hypertension, cardiovascular disease, lung disease, smoking, cancer, kidney disease, or if immunosuppressed. The majority of SARS-CoV-2-infected individuals, particularly, younger individuals, recover completely. A proportion of infected persons go on to suffer from long COVID that manifests as varying persisting signs and symptoms of infection for weeks to months after infection. Long COVID disease can follow either subclinical or clinical disease (37).

Table 1 Severity of disease presentation

Severity of disease presentation	Signs and symptoms
Mild	Fever, cough, fatigue, anorexia, shortness of breath, myalgia. Other non-specific symptoms, such as sore throat, nasal congestion, headache, diarrhoea, nausea and vomiting, anosmia, and ageusia
Moderate	Above symptoms with clinical signs of pneumonia and SpO_2 >90%
Severe	Respiratory distress with SpO_2 <90%
Critical	Acute respiratory distress syndrome (ARDS)

Adapted from: WHO clinical guidelines of grading, 2020.

While not everyone who gets infected gets sick; not everyone who gets ill develops acute respiratory distress syndrome (ARDS) requiring mechanical ventilation. While bilateral multilobular lung involvement was very common in the early cases of COVID-19, we now know that COVID-19 is a multisystem disease affecting human beings from head to toes (Table 2) (38). SARS-CoV-2 is capable of infecting and affecting any organ in which its receptor is present. Angiotensin-converting enzyme 2 (ACE-2) embedded

in the surface membrane of many cells is the functional receptor for SARS-CoV-2 to gain access to human cells. The ACE-2 receptor is highly expressed in lung epithelial cells, kidneys, gastrointestinal tract, liver, vascular endothelial cells, and arterial smooth muscle cells. Thus, all of these organs and systems with high expression of ACE-2 receptors are targets for SARS-CoV-2 infection. COVID-19 may induce a widespread inflammatory response involving all these organs. (39)

Table 2 Multisystem involvement of COVID-19: a disease from head to toe

Organ system	Signs and symptoms
Neurologic	Headaches, dizziness, encephalopathy, Guillain–Barre, ageusia, myalgia, anosmia, stroke
Thromboembolism	Deep vein thrombosis, pulmonary embolism, catheter-related thrombosis
Renal	Acute kidney injury, proteinuria, haematuria
Cardiac	Takotsubo cardiomyopathy, myocardial injury/myocarditis, cardiac arrhythmias, cardiogenic shock, myocardial ischaemia, acute cor pulmonale
Hepatic	Elevated aminotransferases, elevated bilirubin
Endocrine	Hyperglycaemia, diabetic ketoacidosis
Gastrointestinal	Diarrhoea, nausea/vomiting; anorexia, abdominal pain
Dermatological	Petechiae, livedo reticularis, erythematous rash, urticaria, vesicles, pernio-like lesions

Adapted from: Feng, Z., et al *Nature Communications*, 2020, 11(1), pp.1–9.

7.1. Predictors of severe disease and mortality: age and comorbidities

There is growing evidence that COVID-19 can also itself either cause or exacerbate metabolic syndrome (pre-diabetic condition) and hypertension (40). Clinical management for hospitalized patients with COVID-19 is focused on supportive care for complications, including supplemental oxygen and advanced organ support for respiratory failure, septic shock, and multiorgan failure. Most mortality attributable to SARS-CoV-2 infection

occurs through the development of viral pneumonia-induced ARDS. While the exact mechanisms through which SARS-CoV-2 causes ARDS and how certain host factors confer an increased risk of developing severe disease remains unclear, one factor has emerged as a dominant predictor of disease severity and risk of mortality—which is age (41). In an analysis of more than 44,672 confirmed cases by the Chinese Centre for Disease Control and Prevention, the case fatality rate was <1% among <60 years old; 3.6% for those 60–69 years; 8.0% in people 70–79 years; and 14.8% among those 80 years or older (41). Other predictors of disease progression include malnutrition (both underweight and overweight/obesity), and non-communicable diseases (NCDs), including hypertension and diabetes (40, 42).

Infection with SARS-CoV-2 triggers an inflammatory process that can lead to direct or indirect insults to the lung. About 5–15% of patients with COVID-19 infection require intensive care monitoring and ventilatory support, mainly for severe hypoxemia (43, 44). The goal of treatment is maintenance of oxygen saturation >90%. That means supplementation of oxygen via several ways. There are no clear evidence-based guidelines for the ideal time to proceed to mechanical ventilation in patients with COVID-19. Availability of ventilators, intensive care capacity, considerations of palliative care, and end-of-life resources as well as individual patient characteristics all play a role in decisions to institute mechanical ventilation. There are several strategies for delivering oxygen as presented in Table 3.

Table 3 Strategies for delivering oxygen in moderate to severely ill COVID-19 patients

Strategies for delivering oxygen	Indication
Nasal cannula	Effective for mildly hypoxic patients, supplemental oxygen delivered by nasal cannula can induce significant dispersion of exhaled air, even at low flow rates. Supplemental oxygen by nasal cannula provides up to about 5–6 L/min
Simple face mask	Oxygen supplementation via simple mask is only marginally greater than that of nasal cannula. Simple masks provide supplemental oxygen with flow rates up to approximately 5–10 L/min
Continuous positive airway pressure (CPAP)	Delivers pressure through all phases of the respiratory cycle. The patient continues to breathe spontaneously both with and against the positive airway pressure
Mechanical ventilation	Endotracheal tube for patients may be necessary for patients with frank respiratory failure or multisystem organ dysfunction. The machine takes over completely or supports the patients spontaneous breathing
High flow oxygen system	High flow nasal oxygen (HFNO) includes high flow nasal cannula and high velocity nasal insufflation. High flow oxygen systems provide oxygen-rich heated humidified gas to the patient's nose at flow levels sufficient to deliver a constant, precisely set high FiO_2

7.2. Clotting and strokes

Strokes occur when the brain's blood supply is interrupted, usually by a blood clot. COVID-19 causes complications to younger patients being hospitalized for, and sometimes dying from, serious strokes (45, 46). It is unknown if coronavirus itself stimulates blood clots to form, or if they are a result of an overactive immune response to the virus. These strokes are found in patients who test positive for coronavirus but who do not have any traditional risk factors for stroke. They tend to have no COVID-19 symptoms, or only mild symptoms. The type of stroke occurring in these patients typically occurs in much older patients. COVID-related strokes occur because of a body wide increase in blood clot formation, which can damage any organ, not just the brain. A blood clot in the lungs is called

pulmonary embolism and can cause shortness of breath, chest pain, or death; a blood clot in or near the heart can cause a heart attack; and blood clots in the kidneys can cause kidney damage requiring dialysis.

7.3. Long COVID

Fatigue, muscle weakness, insomnia, anxiety, loss of smell or taste persist beyond several weeks for a significant proportion of those infected, including those who were mildly symptomatic. Persistent cardiac symptoms have also been observed. A Norwegian (47) study found at 6 months, 61% (189/312) of all patients had persistent symptoms. Given the short experience (less than two years) with SARS-CoV-2 disease there is still uncertainty about the frequency, manifestations, and severity of persisting COVID-19 disease/long COVID or its management (37). Given the growing cohorts of persons with long COVID, this is becoming an area of increasing concern and requires urgent attention.

7.4. Children and COVID-19

To date, data on COVID-19 in children and adolescents remain scarce. Young people can be asymptomatic or may present with fever, respiratory, and/or gastrointestinal symptoms. Recent studies have demonstrated that COVID-19 is generally a mild disease in children when compared with older patients. It is not yet known what the reasons for the difference in severity of disease are, but three possibilities exist (48): i. Children may have lower viral loads even if they get COVID-19. There may be a correlation between the severity of COVID-19 and the viral loads (or the duration of virus-shedding period); ii. Children have lower expression levels of ACE2, when compared to adults, and, therefore, have fewer receptor sites for the SARS-CoV-2 to bind to; iii. There may be a simultaneous presence of other viruses in the mucosa of the lungs and airways, common in young children, and these viruses may compete with SARS-CoV-2 virus and limit its growth.

A small proportion of children develop a rare, COVID-19 associated multisystem inflammatory syndrome which appears to develop after the infection rather than during the acute stage of COVID19. The clinical features of these paediatric cases are both similar and distinct from other well-described inflammatory syndromes in children, including Kawasaki

disease, Kawasaki disease shock syndrome, and toxic shock syndrome. This COVID-19associated multisystem inflammatory syndrome in children and adolescents is referred to interchangeably as paediatric inflammatory multisystem syndrome temporally associated with SARS-CoV-2 (PIMSTS) or multisystem inflammatory syndrome in children (MISC) associated with COVID19 (49). Symptoms of MIS-C in children include: conjunctivitis; loss of appetite; red, cracked lips or red tongue; enlarged lymph nodes; prolonged fever over several days; diarrhoea and/or vomiting; urticaria; abdominal pain; swollen hands and feet. Of greater growing concern for children is the impact of the death of parents and the increased numbers of orphaned children.

7.5. Treatment

The priority in treatment has been saving the lives of those with severe illness. Currently there are a limited number of drugs that have clinical trial level evidence against SARS-CoV-2. A comparison of the WHO clinical care guidelines (50) to the NIH panel recommendations for treatment of SARS-CoV-2 (Table 4) (51) highlights huge disparities in what drugs can be accessed where leading to huge differences in COVID-19 mortality rates between industrialized countries and LMICS.

The recommendations from the NIH Panel on Treatment for SARS-CoV-2 in terms of the treatment strategy and recommended drugs is dependent on the stage of disease (51). Most infected individuals will have few symptoms and will require primarily symptomatic treatment including rest, fluid replacement, and pain management with non-opioids such as acetaminophen. They do not require hospitalization but may require monoclonal antibodies if at risk of progression. Patients developing respiratory distress and shortness of breath, chest pain, new onset confusion, inability to stay awake, a bluish caste to their face and other signs of hypoxia require hospitalization. Treatment of individuals with more severe disease is based on physician judgement and it may be necessary to put patients on artificial ventilators and oxygen therapy.

Table 4 NIH panel recommendations for treatment of SARS-Cov-2

Patient condition	Treatment recommendation
Mild to moderate symptoms, not requiring hospitalization or supplemental oxygen but at risk of progression	Anti-SARS-CoV-2 monoclonal antibody products such as casirivimab plus imdevimab or sotrovimab. Do not use dexamethasone or other systemic glucocorticoids
Discharged from hospital despite requiring new or increasing need for supplemental oxygen	6 mgs of dexamethasone once daily for duration of supplemental oxygen but less than 10 days
Hospitalized but does not require supplemental oxygen	No corticosteroids. If at high risk for progression may use remdesivir
Hospitalized and requires supplemental oxygen	Remdesivir, remdesivir plus dexamethasone if increasing need for oxygen, dexamethasone if remdesivir not available or contraindicated
Hospitalized and requires oxygen through high flow ventilator	Dexamethasone or dexamethasone plus remdesivir. If systemic inflammation, add baricitinib or tocilizumab
Hospitalized and requires intensive mechanical ventilation or extracorporeal membrane oxygenation	Dexamethasone. If within 24 hours of admission plus tocilizumab

Adapted from NIH guidelines (https://www.covid19treatmentguidelines.nih.gov).

Given the burgeoning of the antiviral drug field in recent years, it was natural for researchers to turn to proven agents successful against other viruses to attempt to treat COVID-19. Data from small observational studies of chloroquine and hydroxychloroquine (CQ and HCQ) looked promising but the UK's adaptive multiarmed randomized controlled trial, RECOVERY (52), and the WHO's multicountry Solidarity treatment trial demonstrated that neither HCQ nor lopinavir/ritonavir had any effect in reducing mortality in COVID-19 (53).

The RECOVERY trial did have a COVID-19 treatment breakthrough in demonstrating that dexamethasone reduced mortality in hospitalized patients on supplemental oxygen. Patients requiring ventilation had a 33% reduction in death. Dexamethasone or its equivalent, e.g. prednisone, is now standard of care for severe, hospitalized COVID-19 patients, worldwide. Hopes for remdesivir, a repurposed antiviral nucleoside analogue first used in Ebola patients, were also high following a US study that showed that it

significantly reduced recovery time if people were treated early (11 days vs. 15 for untreated) but was less effective in severely ill patients (54). The Solidarity therapeutics trial demonstrated no effect of remdesivir on mortality rates in severe COVID-19. There have also been reports of success in reducing the death rate among in severely ill patients by use of infused convalescent plasma, which prompted the FDA in the USA to issue an 'emergency use authorisation (EUA)' to allow hospitals to use it (55).

Monoclonal antibodies are recommended for mild-to-moderate disease but cost and access remain barriers to widespread access. The RECOVERY trial also showed mortality benefit for REGEN-CoV in hospitalized adults (56), RECOVERY (57), and REMAP-CAP (58) have shown benefit of tocilizumab.

There remains controversy about drug use and at what stage of disease they should be used. Of concern is the promotion through social media platforms and by some clinicians of several unproven drugs notably ivermectin and hydroxychloroquine.

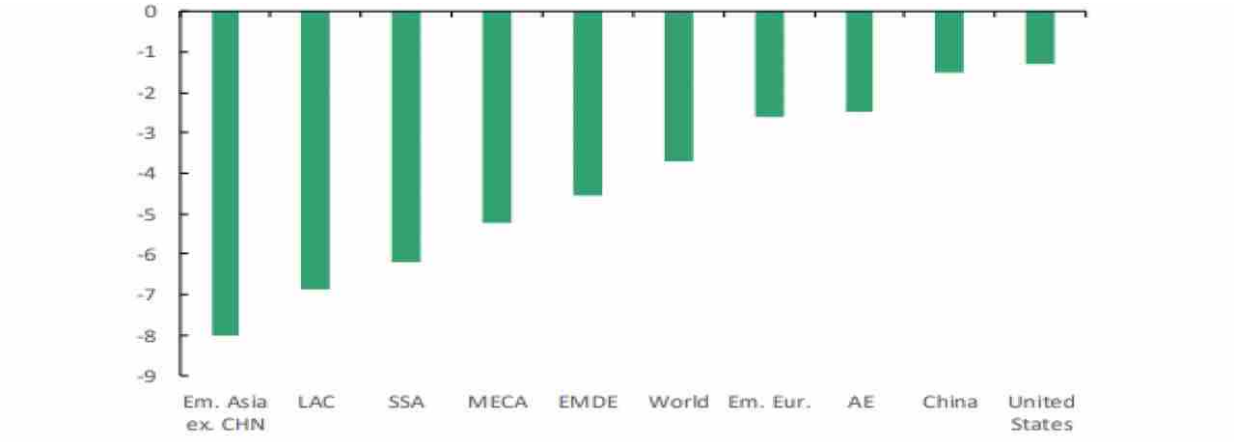
As data from rigorously and robustly conducted trials emerge, the current WHO and NIH treatment guidelines will change. The challenge for benefit will be access. Importantly, in contrast to the substantial investments and advances made in vaccine development (Section 10.2), treatment has had less attention or investments.

8. Social and economic impact of the pandemic

The dichotomy of this pandemic lies in the struggle between saving lives and saving livelihoods. With 90% of the world's countries in recession there has been an unprecedented economic downturn, possibly exceeding even that of the great depression in the 1930s. Some indication of the severity of the social and economic impact of COVID-19 can be gleaned from this quote from the Organisation for Economic Co-operation and Development (OECD): '*The COVID-19 pandemic has triggered the deepest economic recession in nearly a century, threatening health, disrupting economic activity, and hurting well-being and jobs. Extraordinary policies are required to walk the tightrope towards recovery, which will shape the economic and social prospects of the coming decade*' (59).

The COVID-19 pandemic has created an unprecedented economic and public health crisis. The economic impacts have resulted from reduced

productivity, loss of life, business closures, trade disruption, interruption of global supply chains and decimation of the travel and tourism industry (60). The US Congressional Research Service (61) estimates that '… the virus reduced global economic growth in 2020 to an annualized rate of –3.4% to –7.6%, with a recovery of 4.2% to 5.6% projected for 2021. Global trade is estimated to have fallen by 5.3% in 2020 but is projected to grow by 8.0% in 2021'. Further, it notes that the recovery is likely to remain uneven among countries with differences driven by the extent of SARS-CoV-2 vaccine rollout, ability to provide fiscal and monetary support, the extent of hard-hit sectors (especially tourism) and predict that emerging economies will face the most problems because they do not have access to COVID-19 vaccines and have lower resources, providing some indication of how COVID-19 will entrench and deepen existing global economic inequity (Figure 5). While virtually every country covered by the International Monetary Fund (IMF) posted negative economic growth in 2020, the downturn was more pronounced in the poorest parts of the world (62, 63).



Source: IMF-WEO Apr-2021. Note: AE = Advance economies; Emerging Asia ex. CHN = emerging and developing Asia excluding China; EM. Eur = Emerging and developing Europe; LAC = Latin America and the Caribbean; MECA = Middle East and Central Asia; SSA = sub-Saharan Africa.

Figure 5 Global GDP growth 2020.

A McKinsey survey of executives in June 2021 (64) showed that those countries with 'developed' economies were more optimistic about the risk posed by the SARS-CoV-2 pandemic to their domestic growth than those countries with 'emerging' economies—an about turn from their projections

in June 2020. This is most likely because more OECD countries have higher vaccination rates than LMICs.

Yeyati and Filippini (65) note that the pandemic triggered an unprecedented fiscal response in terms of speed and magnitude. Globally, the fiscal support reached nearly USD 16 trillion (around 15% of global GDP) in 2020. They point out that the capacity of countries to implement such measures varied significantly and noted the different capacities country have to support households and firms which depended on access to international financial markets. They also noted that the capacity of states to rapidly and efficiently implement policies to support household and firms, requires substantial state capacity and well-developed tax and transfer infrastructures, which many LMIC do not have.

The report goes on to note that the fiscal and monetary policies of government meant the 2020 economic turndown was not as severe as forecast. These policies included support for businesses to retain workers and additional support for those who were or became unemployed. For instance in March 2021, the UK Government announced a £65 billion stimulus package over two years to revive the UK economy through various business incentives and worker income support measures to be followed by tax increases starting in 2023 (66). At the same time the US Congress passed a $1.9 trillion economic stimulus bill, designated the American Rescue Plan (67). Such moves demonstrated the ways in which the pandemic upended the neoliberal consensus that has been in ascendance since 1990 when UK Margaret Thatcher and US President Regan instituted neoliberal policies which drastically cut public spending and ‘rolled back the state’. This illustrates to what extent a public health crisis can have a dramatic impact on the economic policy of a country.

A congressional report also noted in July 2021 that new variants of the COVID-19 virus and a surge in diagnosed cases in countries like India and Indonesia and resistance to vaccinations among some populations in developed economies means it was hard at that point to predict the speed and strength of an economic recovery.

During the pandemic there were passionate debates about whether the economic sacrifice necessary to impose public health control measures would create more health problems than the pandemic (68). Such dilemmas are not new in public health where those who perceive a loss of profits often oppose public health constraints. The experience of countries where public

health measures were not taken (e.g. Brazil and the USA in 2020) demonstrate that the result is a very high death toll and causes extreme pressure on health systems. Ultimately the decision of whether to protect health rather than profits is a moral one. Public health ethics dictate that health is the primary consideration.

The COVID-19 pandemic has laid bare the many inequities that existed before it started. The Independent Panel for Pandemic Preparedness and Response report in May 2021 (69) captures this as follows: 'The lack of planning and gaps in social protection have resulted in the pandemic widening inequalities with a disproportionate socioeconomic impact on women and vulnerable and marginalized populations, including migrants and workers in the informal sector'. These inequities concern those within as well as between countries and reflect structural drivers of ill-health. The inequities between countries have been most noticeable in the vaccine distribution, drugs, and equipment necessary to diagnose, prevent, and treat COVID-19; this is discussed in greater detail next. Vaccine inequities, for example, will lead to a range of social and economic inequities affecting countries' ability to return to more normal life, thereby exacerbating the existing inequities between these countries.

Within countries inequities were also apparent according to: ethnicity and race; being a migrant or refugee; employment and economic status; gender. While limited data are available largely from small studies with several confounders the intersection of race, gender, and deprivation or marginalization is not surprising.

8.1. Ethnicity and race

Globally, COVID-19 has shown a strong tendency to affect minority populations more than other groups. Table 5 shows that in the US while Black, Indigenous peoples, and Hispanic or Latino populations were only slightly less likely to get COVID-19, they were much more likely to be hospitalized or die from it. The Centers for Disease Control and Prevention (CDC) notes that race and ethnicity are risk markers for other underlying conditions that affect health, including socioeconomic status, access to healthcare, and exposure to the virus related to occupation, e.g. frontline, essential, and critical infrastructure workers. In the UK the ethnic and racial differences have been reported as being even greater, as illustrated in a

prospective cohort study that demonstrated a more than 4-fold higher risk of COVID hospitalization for Blacks vs. a 2-fold increased for Asians and other non-white groups compared to whites, after adjusting for age and sex (70).

Indigenous peoples are at greater risk of harm from COVID-19 primarily because of their existing poorer health status, and because 'they have been made fragile by the legacy and persistence of colonial practices'. In Brazil, where the overall death rate was already one of the highest in the world, for Indigenous people the death rate was even higher (71). It is notable that Aboriginal Community Controlled Health Services in Australia have been very successful in protecting the health of Aboriginal people, especially those living in remote areas through developing a range of resources and a National Management Plan for Aboriginal and Torres Strait Islander Peoples (72). This suite of measures to protect population groups with many vulnerabilities has been demonstrably effective.

Table 5 Risk for COVID-19 infection, hospitalization, and death by race/ethnicity—United States, July 2021

Race and ethnicity are risk markers for other underlying conditions that impact health				
Rate ratios compared to white, non-Hispanic persons	**American Indian or Alaska Native, Non-Hispanic persons**	**Asian, non-Hispanic persons**	**Black or African American, non-Hispanic persons**	**Hispanic or Latino persons**
Cases	1.6×	0.7×	1.1×	2.0×
Hospitalization	3.3×	1.0×	2.9×	2.8×
Death	2.4×	1.0×	2.0×	2.3×

8.2. Migrants and refugees

Refugees and migrants have been disproportionately affected by the SARS-CoV-2 pandemic. WHO reported that the pandemic has triggered many different adaptation policies related to international migration that affect

public health, directly or indirectly. They note that the overall picture is ‘highly complex and disparate, as national reactions to the global pandemic vary considerably in both nature and scale, impairing, in turn, a truly coordinated and consistent public health response’ (73). In addition to experiencing a range of health conditions including NCDs, mental health, and a high rate of injuries, they also may also experience highly insecure living conditions and lifestyles. Very often they also suffer discrimination, poverty, poor housing and education, poor employment practices, often without access to essential health and other services including to COVID-19 vaccines. WHO stresses that better international coordination is required to safeguard the human rights of refugees and migrants and this is particularly the case given the additional stress of the COVID-19 pandemic.

8.3. Employment and economic status

The International Labour Organisation reported in 2021 that the COVID-19 pandemic has caused unparalleled disruption to employment and livelihoods worldwide. Workers whose labour market position was disadvantageous prior to the crisis—women, young people, migrants, informal workers, and workers in lower-skilled occupations—suffered disproportionately (74). People working in casual and informal employment have been more likely to be exposed to COVID-19. Some forms of work pose multiple risks (see Figure 6 for the example of meat workers). The case of meatworkers highlights the ways in which a range of vulnerabilities—casual work, migrant status, low wages, home environment, low occupational health and safety conditions—converge to make a particular group of workers very vulnerable to COVID-19.

- Significant Covid-19 outbreaks have affected meat workers in Brazil, the UK, USA, Ireland, France, Australia and Germany. (75)
- Under “normal” circumstances, working conditions in slaughterhouses cause workers mental, psychological and physical harm (76) and Covid-19 intensifies these existing health risks.
- Many meatworkers workers are immigrants and refugees who may be undocumented and at risk of deportation and so are reluctant to unionize or challenge exploitative labour practices (77-79)
- Additionally, workers are often dependent on their employers for housing and sometimes transport (80, 81)
- Their relatively low wages, and the housing discrimination that racial minorities, low-income and immigrant workers face, constrain their ability to seek alternative housing.
- The physical configuration of slaughterhouses (i.e. working in close proximity, the need to shout to be heard) and communal housing and transport make social distancing near impossible (82)

Figure 6 Meatworkers and susceptibility to COVID-19

8.4. Gender

A study in China found (83) that while men and women have the same prevalence, men with COVID-19 are more at risk for worse outcomes and death, independent of age. A global data base (84) reveals that females are more likely to get tested (57% of those tested are female), equally likely to be diagnosed with COVID-19 (50% of cases), less likely to be hospitalized (48% of hospitalizations), less likely to be admitted to an ICU (31% of admissions), and less likely to die (43% of deaths) compared with males. In terms of social determinants (which will affect health in the longer term) the impacts of pandemic-induced social and economic change appear more severe for women. Nearly 40% of employed women work in the hardest hit industries including the informal sector, which is dominated by women workers (85). There are approximately 740 million women working in the informal sector and their incomes saw a 60% reduction in the first month of the pandemic (86). Other affected female-dominated sectors include arts and entertainment, accommodation and food services, wholesale and retail trade and manufacturing (garment industry). Women also provide three-quarters of unpaid care work that has increased due to closure of schools and childcare services, increased care needs for aged and overwhelmed health systems (87). A UN Women report (88) highlights the intensification of violence against women as a result of COVID-19 containment measures and as the economic impact starts to unfold. Of concern is that globally 243 million women and girls aged 15–49 years have been subjected to sexual or physical violence perpetrated by an intimate partner and describe this surge in

violence against women and girls as a ‘shadow pandemic’ linked to COVID-19 and call for national COVID-19 responses to include services to mitigate this pandemic.

8.5. Healthcare workers

Health workers are one group of workers who are at high risk of contracting COVID-19. The Independent Panel for Pandemic Preparedness and Response (69), notes that at least 17,000 health workers died of COVID-19 in the first year of the pandemic and said this underscored the need for countries to do much more to support and protect them. Of note is that 70% of those employed in health and social work are women and they often hold lower-skill and lower-paying jobs. Their working conditions put them at greater risk of infection, especially in LMICs (89). Community health workers (CHWs) are mostly women, and often from rural and lower socioeconomic backgrounds, paid irregular salaries/stipends/incentives, especially in LMICs. CHWs have been an essential part of the pandemic response and they have played a crucial role in public health systems. They have undertaken COVID-19 surveillance, contact tracing, monitoring quarantine and isolation, along with their regular tasks. Despite the high risk, they often work without adequate PPE or training (90, 91, 92).

8.6. Children

UNICEF estimates 42–66 million children could fall into extreme poverty as a result of the pandemic adding to 386 million children already in extreme poverty in 2019 (93). With the second, third, and fourth surges mortality rates have increased in 40–60-year-old people who are typically the main breadwinners and likely have young children. The impact of premature loss of lives on child orphans remains to be quantified.

8.7. Digital divides

When many are confined to the home and many workplaces are forced to convert employees to working from home, the divide between those with internet access and the necessary technology to continue their work remotely and those that don’t becomes even more pronounced. Under the

circumstances of the COVID-19 pandemic, individual access to information is critical for coping both with work for breadwinners, and with education for young children looking to further their prospects in life. Roughly 60% of the global population has internet access however, in sub-Saharan Africa, 82% of students do not have internet access and 90% don't have access to a household computer (94). Putting percentages into more direct numbers, there are more than twenty-one million people in South Africa alone who do not have internet access. (95).

8.8. Mitigating the impact of COVID-19

A Congressional report (96) estimates that 95 million people may have entered into extreme poverty in 2020 with 80 million more undernourished compared to pre-pandemic levels. The International Labour Organization (ILO) (97) identifies four pillars of action designed to lessen the impact of COVID-19 on businesses, jobs, and people in vulnerable circumstances: i. Stimulation the economy and jobs; ii. Supporting enterprises, employment, and incomes; iii. Protecting workers in the workplace; iv. Using social dialogue between government, workers, and employers to find solutions. The ILO views these pillars as vital to using the response to COVID-19 as a chance to ensure decent working conditions.

9. The colliding pandemics of HIV and SARS-CoV-2

SARS-CoV-2 is one of several pandemics facing humanity today. Here we focus on HIV noting that advancing HIV disease is closely intertwined with Tuberculosis and sub-Saharan Africa bears a disproportionate 70% of the global burden of HIV infection (see Chapter 8.13, Acquired immunodeficiency syndrome [AIDS], for more details). Importantly, in recent times, the global response to the HIV pandemic set a precedent in responding to pandemics, for example, the establishment of UNAIDS (the joint United Nations Programme for HIV/AIDS). This new global solidarity to responding to global health crises supplemented with substantial multilateral and bilateral collaborations and capacity building efforts enabled global equity for access to affordable life-saving anti-retroviral treatment that transformed AIDS from an inevitably fatal condition to one that is chronic and manageable. Substantial increases in life expectancy in excess

of 12–15 years particularly in countries in Africa have been achieved since the establishment of the Global Fund for AIDS, TB, and Malaria and the USA President's Emergency Program for AIDS Relief (PEPFAR) (98). In 2020 there were approximately 38 million people living with HIV, 690 thousand deaths, 1.5 million new infections, 32 million HIV-infected individuals on treatment and transmission rates to infants reduced to <2% (99). Despite predictions early in 2020 that sub-Saharan Africa would be devastated by SARS-CoV-2 that did not happen during the first surge of infections (6, 7). However, since the latter half of 2020, with each new surge of SARS-CoV-2 infections the impact on sub-Saharan African countries has worsened. The ongoing HIV pandemic in the midst of the emerging and evolving SARS-CoV-2 pandemic provides important insights on addressing parallel pandemics and the potential cost and short-sightedness of abandoning work on an existing pandemic in favour of a new pandemic.

9.1. The use of existing resources

The technology, infrastructure, and systems developed to control and treat HIV served as a springboard to accelerate the response to COVID-19 in Africa. For example, diagnostic equipment such as PCR and gene-expert platforms have become commonplace in primary healthcare clinics and other health settings for HIV viral load testing and enabled the rapid rollout of SARS-CoV-2 RT-PCR diagnostic testing. The community outreach programmes developed for HIV and TB contact tracing and case management enabled the rapid mobilization of hundreds of thousands of healthcare workers in Africa to assist in COVID-19 education, screening, testing, contact tracing, isolation, and quarantine efforts. Similarly, the overall strengthening of healthcare delivery systems and human resource capacity to enable massive rollout of anti-retroviral (ARV) treatment for AIDS patients facilitated rapid pivoting in health facilities to deal with the large numbers of severely ill COVID-19 patients. Clinical staff already trained in infectious diseases meant that there was a critical mass of skilled personnel who could and did provide expert advice to guide national and local responses to COVID-19 across Africa. The same genetic sequencing platforms designed to monitor trends in ARV drug resistance and understand HIV viral transmission dynamics (100) enabled a faster and more reliable identification of variants of SARS-CoV-2 and rapidly strengthen molecular

surveillance efforts including for outbreak investigations (101, 102). Clinical trial infrastructure developed to evaluate HIV prevention technologies, including potential HIV vaccines, pivoted rapidly to evaluate COVID-19 vaccine trials and establish COVID-19 vaccine rollout platforms (103).

9.2. The complications of two concurrent pandemics

In many countries in Africa, interventions to prepare for the anticipated increase in hospitalization for severe COVID-19 cases or to slow the spread of SARS-CoV-2 such as national lockdowns had unanticipated negative effects on responses to HIV. For example, testing and treatment for both HIV and TB dropped substantially as patients were apprehensive about visiting a clinic or hospital where they faced the risk of acquiring SARS-CoV-2 or where access to these services were restricted. This increases the risk of new infections, and/or the emergence of drug-resistant variants of HIV because of ARV treatment interruptions. While there is limited data to quantify the magnitude of these effects, a study undertaken in South Africa during national lockdown showed that weekly testing for HIV viral loads dropped by 22%, and CD4+ cell count monitoring dropped by 33% (104). In addition to this impact on HIV patients in care in public sector health facilities, the number of new HIV tests being done each month declined nearly 50% during lockdown, as did the number of antiretroviral treatment (ART) initiations negatively (105) impacting the country's efforts to reach the '90–90–90' targets towards achieving the UN 2030 goal of achieving epidemic control of HIV (106). Notably there were no marked changes in ART collections suggesting that those patients already on medication remained adherent (105). Access to other essential services such as pre-natal care, access to sexual reproductive health services, and other chronic conditions were also severely restricted. However, innovations of multi-month dispensing, community collection points for medication, and community-based buddy/peer adherence support clubs ensured continuity of care and minimized treatment interruptions for HIV and other chronic conditions (107).

9.3. Does HIV enhance the risk of acquiring SARS-CoV-2?

Given that HIV attacks the immune system of infected individuals, this is an important question. The answer to this question was a bit more complicated for several reasons. Firstly, in contrast to Africa, industrialized countries have low HIV infection rates that are concentrated in key populations (99). Therefore, in the first half of 2020 little data was available on whether HIV was a risk factor for SARS-CoV-2 infection. Secondly, 65% of the population in Africa is under 35 years old and for most of 2020 for SARS-CoV-2 infection, older age was regarded as an important risk factor and this partly explained why the number of infections in Africa remained relatively low (6, 7). However, as SARS-CoV-2 infection became more established in Africa, data on HIV risk has started to emerge (108, 109, 110). These data suggest that HIV positive individuals (PLHIV) who are virally suppressed as a result of being an ART and who have immune reconstitution viz a CD4 count >500 have a similar risk of acquiring SARS-CoV-2 as HIV uninfected persons. However, PLHIV who are not on ARV treatment or have treatment interruptions, or have low CD4 counts (i.e. severely immunocompromised) and high HIV viral loads were more likely to acquire SARS-CoV-2 infection; shed SARS-CoV-2 for longer durations and experience a more severe clinical course of COVID-19 (108). Specifically, PLHIV with low CD4 cell counts, or untreated HIV infection have higher mortality rates, and those with CD4 counts<200/ml have higher rates of ICU admissions that require mechanical ventilation. A retrospective study conducted in the USA (109) found a 2.9-fold higher death risk for patients living with HIV, with a 2–4-fold confidence interval. Of note in this study was that individuals in this cohort who were Black, male, and economically deprived, had 4.3-fold higher mortality rate compared to the 1.8-fold higher mortality rates noted for other HIV infected persons (109). At least 8% of COVID-19 deaths are attributed to co-infection with HIV (111, 112, 113).

9.4. Uncontrolled HIV infection fuelling the evolution of SARS-CoV-2 variants of concern and compromising vaccination efforts

Individuals with advanced HIV and ART failure or who are on treatment but still immune-compromised (i.e. CD4<500) are likely to have prolonged COVID-19 infection. This extended COVID-19 infection can be reduced with effective HIV ARV treatment and once immune reconstitution reaches

CD4 counts >500 it results in clearance of SARS-CoV-2 infection (114). However, while HIV infection persists, SARS-CoV-2 replicates freely and mutations constantly emerge within those immunocompromised patients. This is clearly demonstrated in the early emergence of the N501Y transmissibility substitution and escape mutations such as the E484K substitution HIV infected patients (114). A HIV stratified analysis in a matched case-control study demonstrates that substantially lower concentrations of both IgG and pseudo-virus neutralizing antibody titres after SARS-CoV-2 infection in PLHIV, that might explain the diminished immune response to SARS-CoV-2 infection (115).

What are the implications of a compromised immune response in HIV infected for vaccine efficacy? Preliminary data from a longitudinal analysis of a severely compromised HIV infected patient with uncontrolled viraemia (VL >800,000 copies; CD4< 20 cells/ml) showed no response after two doses of the BNT162b2 vaccine (116). The patient had no IgG reaction against the spike protein, no SARS-CoV-2 specific neutralization, and no quantifiable spike protein specific T cells. Given the high burden of HIV infection in sub-Saharan Africa, this has important implications for COVID-19 vaccination efforts suggesting that an additional vaccine dose is needed in this group and should be considered in the ongoing responses to the SARS-CoV-2 pandemic. Of note is more recent data demonstrating that with well-controlled HIV, similar immune responses are observed as in HIV uninfected persons (117, 118) underscoring the importance of strengthening efforts to increase HIV testing, treatment initiation in those infected with HIV, and ensuring viral suppression rates in those initiated on treatment as we increase SARS-CoV-2 vaccination efforts.

10. Ending SARS-CoV-2: An evolving endgame

As many countries have pondered their post-COVID-19 recovery plans, the public health goal has shifted from herd immunity, that is, sufficient numbers of individuals being exposed to SARS-Cov-2 and who have recovered; to high vaccination coverage rates combined with natural immunity to stop community spread; to natural immunity, vaccination, and slowing the emergence of variants of concern. Each of these key concepts are elaborated on next in relation to COVID-19. For now, the virus appears to have the upper hand but we need to continue our efforts to get ahead of it. With

pandemics in the past such as smallpox or polio, global efforts with vaccine availability have focused on elimination of the presence of the organism in humans. In the case of SARS-CoV-2, will the goal be epidemic control as with the UN2030 HIV goal, i.e. the numbers of infection reach sufficiently low levels for it to no longer pose a public health threat? The repeated surges of infection globally usually triggered by the emergence of a variant of concern, each more infectious than the last, suggests that we are dealing with greater complexity of transmission dynamics than we have ever known.

10.1. Role of herd immunity

Herd immunity is an inflection point in an epidemic or pandemic where sufficient people in a country or globally are protected from a disease and the virus can no longer spread within a population. This can result from natural recovery from infection and/or from vaccination and/or from the adoption of other public health and social interventions as described in section 4, earlier. Early in the pandemic some countries such as Sweden (119) used the concept of natural recovery from infection to define their SARS-CoV-2 response. A challenge with natural immunity or vaccine-induced immunity is that we don't yet know for how long that protection lasts. In mid-2021 some reports of re-infection with COVID-19 started to emerge (120). We now know that there is wide variability in SARS-CoV-2 transmission depending on the environment and R_0 only applies to a population that has no natural or vaccine-induced immunity or widespread adoption of other prevention measures such as mask wearing; physical distancing; and hand washing that reduce the risk of getting infected and the rate at which people get infected. In 2020 using the highest transmission rate estimate of 3 for COVID-19; a herd immunity level of 67% was estimated to be needed to slow down viral spread within the community (121). But, because viruses evolve over time, have different levels of infectiousness and new variants emerge, and we don't have vaccines that are 100% efficacious or prevent infection, R_0 is not static, and the herd immunity level will need to be higher than 67%, some estimate closer to 100%.

10.2. Vaccines

Based on prior experience with pandemics, the development and rollout of an efficacious vaccine was regarded as the most effective approach to control the SARS-CoV-2 pandemic (122). During the early stages of the pandemic, many expressed scepticism that an effective vaccine would soon become available, pointing out that time period from initial vaccine development through a series of trials and finally to approval often takes over a decade. Yet despite the many obstacles, several highly efficacious and safe vaccines have emerged in less than a year (123, 124, 125). A major reason for this is that pharmaceutical companies, in many instances with substantial financial support from governments, have compressed the timeline by overlapping many of the phases of this process through novel adaptive study designs. To facilitate access, the infrastructure for producing vaccine in massive quantities was put in place even before the success of clinical trials was demonstrated, and actual production in mass quantities of vaccine preceded approval and, in some cases, the final results of clinical trials. From a financial point of view, such a compressed timeline entails considerable extra risk, in case the vaccine fails. But many governments were willing to subsidize these risks given the considerable social and economic losses that result from a continuation of the pandemic.

The accelerated development for COVID-19 vaccines was also made possible because several scientists had already been working either with related coronavirus vaccine candidates, for example the Middle Eastern respiratory syndrome coronavirus (MERS-CoV) or the original severe acute respiratory syndrome coronavirus (SARS-CoV-1) and were able to rapidly replace inserts of SARS-CoV-2 genes or proteins; or had well-developed vaccine ‘backbones’ like those for measles and flu vaccines, making it easy to adapt them for COVID-19 (126). These factors, and the willingness to adapt the traditional clinical evaluation pathway to allow concurrent Phase 1/2 and 2/3 testing, meant that development time could be reduced to as little as 10 months to a year. Thus, within less than a year of the global report of the pandemic, several effective vaccines had been developed by several corporations in collaboration with the US, the UK, and other government agencies globally. Over 150 vaccines were under development in 2021 (127).

Several approaches have been used by different producers including: **i. Genetic vaccines**, consisting only of RNA or DNA encoding the spike protein, or the main virus particle outer protein; **ii. ‘Killed’ or inactivated**

whole virus particle vaccines; iii. Subunit, or nanoparticle, vaccines, which consist only of the spike protein made in a recombinant expression system; **iv. Live virus vaccines**, such as several different kinds of adenoviruses or measles vaccine or vesicular stomatitis virus (VSV, also used for Ebola) that carry the gene for spike protein; and **v. Attenuated vaccines**, with the live modified SARS-CoV-2 virus itself.

Table 6 presents vaccine efficacy by vaccine type. The AstraZeneca and Johnson & Johnson (J&J) vaccine efficacy varied by trials and country in which the trials were conducted (128, 129).

Table 6 Vaccine type, producer, and efficacy

Vaccine type	Company (vaccine)	Efficacy (pre-existing variants)
mRNA (123, 124)	Pfizer BioNTech (BNT162)	92%
	Moderna (mRNA-1273)	>90%
Viral Vector (129, 130, 125)	J&J (Ad26.COV2-S)	64–72%
	Gamaleya (Sputnik V rAd5, rAd26)	92%
	Oxford-AstraZeneca (AZD1222)	67–76%
	CanSinoBio (Ad5-nCoV)	65%
Spike Protein	Vecttor Institute (EpiVacCorona)	Unknown
	Novavax (NVX-CoV2373)	89%
Inactivated Virus	Sinopharm	78%
	Sinovac	51–84%
	Sinopharm-Wuhan	73%
	Bharat Biotech (BBV152)	78%

The level of efficacy for all the trials completed to date and reported earlier is based on protection against severity of COVID-19 clinical disease rather than preventing infection with SARS-CoV-2.

10.2.1. Vaccination and global equity in access to vaccines

The increasing number of safe and efficacious vaccines are an important starting point to control of the pandemic. However the potential of vaccines can only be realized by global equity in access and ensuring the sufficient numbers of individuals globally are vaccinated.

Notwithstanding the many formidable challenges of developing, testing, and licensing a vaccine we now have a growing number of safe and efficacious vaccines (Table 1). Continuing large-scale manufacture and distribution requirements pose new and equally formidable challenges depending on the types of vaccines. Those merely requiring a live virus to be grown, such as the adenovirus-based candidates, are probably the easiest to produce as the volume of material to be produced is less than for subunit vaccines, which typically require much more material to be made and purified as they are not infectious. Killed vaccines are one of the quickest ways to make the product, but this requires that a very large amount of live, virulent SARS-CoV-2 be grown. This is problematic due to the stringent safety requirements imposed when working with live unmodified virus (131). The production volumes required for the non-live vaccines are such that the world may simply not have the capacity to make the required amounts in less than a couple of years to protect the majority of persons globally (132).

Distribution is also potentially a problem, as certain of the vaccines require refrigeration to as low as –80° C for storage and transport, which may pose a serious obstacle for rolling these out to remote locations especially in LMICs. Of note is that with the exception of the J&J vaccine, which requires only a single dose, most of the other available efficacious vaccines require at least two doses for full protection. It remains to be seen how manufacturing capacity is scaled up and the geopolitical issues of vaccine distribution are handled (133).

The rapid dissemination of the vaccines, primarily in wealthy countries, has had a dramatic effect in reducing the transmission of SARS-CoV-2 and has caused the lifting of lockdowns in many areas. An expected surge in transmission accompanied the loosening of restrictions has occurred but the surge is higher in communities with low vaccination rates. Although the level of persons vaccinated has not reached a level to achieve ‘herd immunity’, the dissemination of vaccinations has had a dramatic effect at reducing the transmission of SARS-CoV-2. Underscoring the importance of

being vaccinated, 99% of persons dying in the United States in mid-2021 had not received a vaccination (134). Data from the UK demonstrates substantial reductions in mortality rates in the current wave of infections compared to the second wave that correlates with their high vaccination coverage rates (Figure 7) (135). If a vaccinated person gets infected, while they may not experience severe disease they may unknowingly transmit the virus, especially if they are asymptomatic. Some emerging data underscore the importance of vaccination for breaking chains of transmission, for example, in a study from Israel that included 253,564 individuals in 65,624 households there was a 79% reduction in infection in those exposed to vaccinated household contacts compared to unvaccinated infected household contacts (136). At a community level there is evidence that with each 20% increase in vaccination there is a 50% decline in test positivity rate in unvaccinated people (137). These data underscore the importance of enhancing access to vaccines and high vaccination coverage rates in our efforts to curb the spread of SARS-CoV-2 and have some return of ‘normality’ globally.

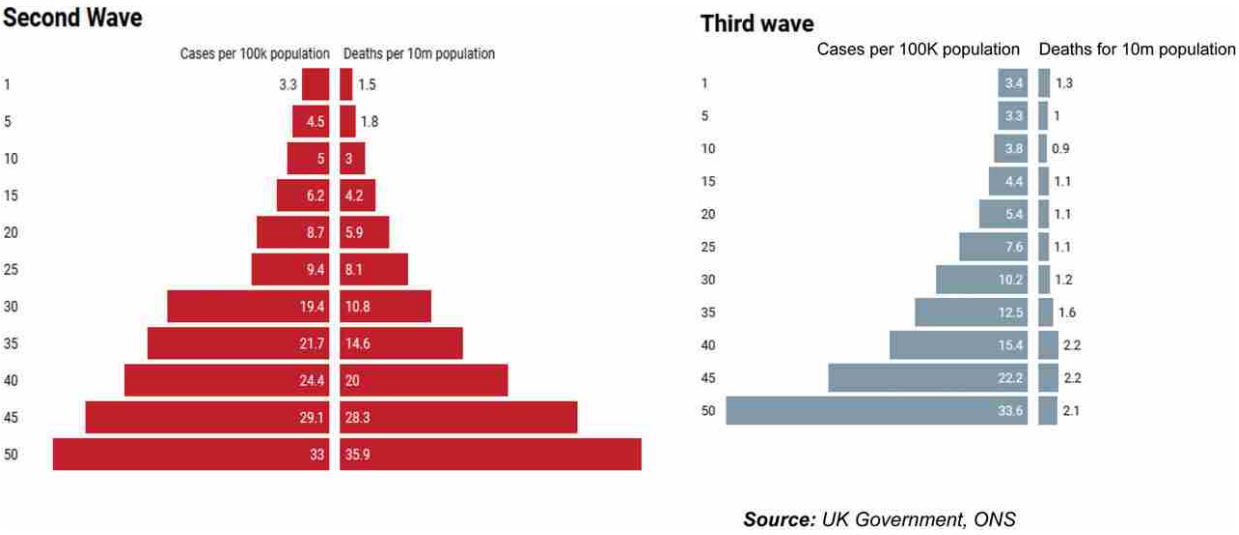

Figure 7 Impact of vaccination on hospitalization rates in the UK with circulation of Delta variants. Adapted from: UK Open National Statistics.

Unfortunately, in some countries where vaccines are available, a substantial proportion of the population is reluctant to be vaccinated. Some of the reluctance stems from hesitancy emanating from the rapid production

of the vaccine (138). However, as increasing numbers have been safely vaccinated confidence in their safety is growing and many have become vaccinated. Various forms of incentives are also having an impact on those who are hesitant. In some settings such as workplaces or travel to other countries, evidence of vaccination is becoming a requirement. While no country has yet made vaccination mandatory, an increasing number of sectors have started to institute vaccine mandates.

Of greater concern is the 'anti-vaxxer' movement whose anti-vaccine stance preceded SARS-CoV-2 and has now become more complex (139). At heart are underpinnings of mistrust in government, science, supremacy, and interpretation of individual rights. While their presence was initially observed in industrialized countries the dissemination of misinformation about vaccines and vaccinations spread through the social media platforms and conservative news stations is expanding to LMICs (140). Of concern are 'anti-vaxxer' rallies and marches occurring in many countries with a disregard for any of the public health preventative measures particularly use of masks and social distancing.

Politics and panic have caused major disruptions in the distribution of vaccines to where they are needed with vaccine nationalism at the forefront. Vaccine nationalism involves: buying more vaccines than necessary; striking deals with pharma to redirect doses away from equity groups; negotiating bilateral deals and queue skipping by paying more and thus pushing prices higher; rushed regulatory approval of vaccines despite inadequate data available; and bans on export of vaccine by the manufacturing countries. These actions and the diversion of vaccines away from LMICs will cost rich countries the most. Review of the global vaccine rollout in mid-2021 reveals that just 10 countries have received 75% of the vaccine doses that have been administered, while the remaining 170 countries share only 25% of global vaccine doses (141) (Figure 8). Only a small fraction of the world's population has been vaccinated, even in the affluent developed countries. The fraction of people having received at least one vaccine dose in the USA and the UK are 49.6% and 41.8%, respectively, whereas in Africa it is <2% (142). By 15 August 2021, 4.7 billion vaccine doses were administered and 1.9 billion people were fully vaccinated (143).

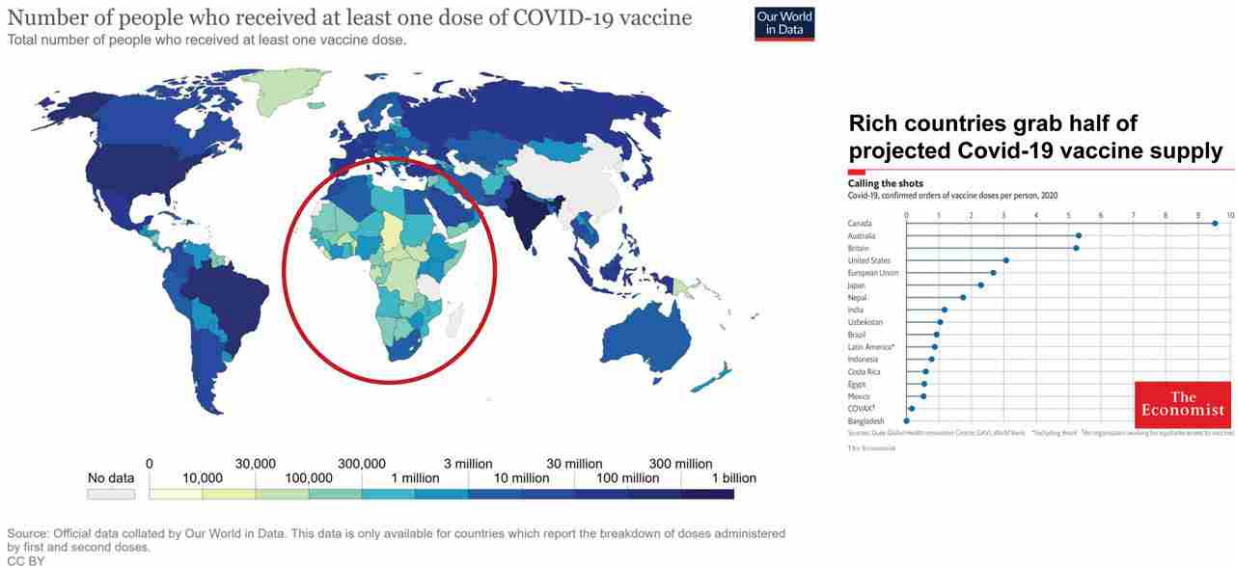

Figure 8 Vaccine nationalism defining who has vaccine access
Source: Official data collated by Our World in Date. This data is only available for countries which report the breakdown of doses administered by first and second doses.

Civil society groups around the world and some LMIC countries have been campaigning for a waiver to the World Trade Organization's intellectual property rights through a waiver of the Trade-Related Aspects of Intellectual Property Rights (TRIPS) agreement (144). A major boost was given to their campaign when President Biden announced that the USA would support the waiver and more recently his commitment to distributing over 200 million doses of vaccines to LMICs through Covax are important contributions to increase vaccine access to LMICs. Yet the world continues to be starkly divided in terms of equal access to vaccines and civil society groups continue to advocate for more equitable access. On Twitter, the hashtag #vaccineequity has been trending demonstrating the moral concern about the maldistribution of the vaccine. Laudable access efforts include the European Union's commitment to building vaccine production capacity in Africa in partnership with the African Union through the Africa CDC bringing some hope for future pandemic preparedness and represents an important commitment for building global capacity and strengthening local resilience. Notably it highlights recognition by wealthy countries of their global responsibilities (145). Notwithstanding, bilateral and public-private agreements, a recent *New York Times* report that of 90% of J&J vaccine produced in South Africa was shipped to Europe contrary to pre-production commitments made to the South African government in their export permit

applications that indicated that export permit waivers were needed to facilitate vaccine distribution in LMICs through Covax (146). This type of corporate greed contributes to distrust in the public and LMIC governments in industry.

Notwithstanding efforts to bridge global disparities in vaccine access, the hope and optimism from vaccines as a gateway to return to pre-COVID-19 normality is being further compromised by the emergence of new and more potent variants of concern that are infecting fully vaccinated individuals, which is described next.

10.3. Variants of concern

For viruses, mutations occur naturally during replication. The majority of these mutations are minor and do not impact viral functioning or structure. However, sometimes the mutation can result in a substantive structural or functional change to the virus that enhances transmissibility, virulence, or alternatively leads to extinction of the virus.

With the rapid transmission of SARS-CoV-2 resulting in millions of replication events many variants have evolved in several areas of the world. For example, the Alpha variant first described in the UK, the Beta variant first described in South Africa, the Gamma variant first described in Brazil, the Delta variant first described in India, and the Epsilon variant first described in California (147, 148, 149). Variants can occur via multiple pathways. Naturally SARS-CoV-2 has a slow genetic drift of 1–2 mutations a month, occasionally this same genetic shift will incorporate multiple mutations and thus create a variant. Persistent long-term active infection in immunocompromised individuals is an important source of new variants wherein antibody treatment or vaccination can create variants with immune escape. The majority of new variants have no functional advantage and so die off before spreading widely, though occasionally a new variant does have a functional advantage such as higher transmissibility that allows it to spread faster and become the dominant variant. These new variants may also be more pathogenic for humans.

Variants have been classified into two categories (150): i. variants of interest (VoI), and ii. variants of concern (VoC). A VoI can be raised to a variant of concern if it spreads faster and causes more serious cases or deaths. Typically, identification of VoI is based on a laboratory identification

of biological mutation that may potentially causes infectiousness or severe disease in a small number of patients. A VoI can be recategorized as a VoC when it spreads more widely within populations; spreads faster, or causes more cases of death, and/or infects large proportions of vaccinated people.

Variants of interest have been identified in the USA, the UK, Brazil, and India. Variants of concern have been identified in the UK, South Africa, and Japan, and Brazil. The range of reductions in neutralization activity to convalescent sera relative to the original Wuhan strain have ranged from <2-fold to as high as 12-fold (151). The vaccine efficacy against individual variants has ranged from 10% (AstraZeneca) to 90% (Pfizer) depending on the variant, the country reporting, and the outcome being measured, e.g. mild–moderate or severe disease (152). The current vaccines are thought to provide an adequate level of protection against the currently known variant strains although there is concern about the need for ongoing surveillance for variants that may escape in vaccinated individuals as well as immunocompromised individuals (153).

In November 2020, scientists in South Africa identified the 501Y.V2, B.1.351, or the Beta variant that coincided with the emergence of the second surge of SARS-CoV-2 infections in South Africa that was worse than the first wave of infections. The E484K mutation that resulted in the Beta variant occurs at the binding domain and helps the virus to evade antibodies produced by the body's immune system. This immediately raised questions around whether current vaccines will work to protect people from the Beta variant and its implications for continued spread. The Beta variant can significantly evade immunity from previous infection thereby resulting in many cases of re-infections and increased household transmission resulting in higher rates of hospitalizations from severe disease. In other words, the rise of new variants poses a problem for reaching herd immunity, as the more infectious the virus becomes, the more people need to be protected in order to stop the virus from spreading. There are also implications for vaccine-induced immunity. This was, for example, seen in the trials for the AstraZeneca and J&J vaccines that were undertaken while the Beta variants were in circulation in South Africa (154). The rapidity of the spread of the Beta variant across Africa within a matter of weeks also highlight our interconnectedness and vulnerability and why we need equity in access to and coverage rates of interventions such as vaccines. Only a handful of COVID vaccine manufacturers have released results from their clinical trials

and received emergency use approval in countries such as the United States, Israel, and the UK. All of these vaccines rely on our bodies identifying the spike protein on the surface of the coronavirus as a way of producing an immune response. We are starting to see second- and third-generation variants emerge, e.g. the Delta variant is a variant to the Beta variant.

From March to June of 2021, a severe outbreak of the Delta variant in India resulted in a substantial surge in India followed by noticeable increases in infections globally even in countries with high vaccination coverage rates. The new surges in infection experienced globally in 2021 are being driven by the Delta variant (6, 7). In the USA for the first time since February 2021, there were more than 100,000 cases per day reported in August 2021. Similar scenarios are emerging in Australia, New Zealand, China, and several countries in Africa. There was initial evidence suggesting that the variant reduces vaccine efficacy. Preliminary data from England shows that the effectiveness of both the Pfizer and AstraZeneca vaccines had been lowered after one dose from 51.1% to 33.5% that was offset following the second dose—the AstraZeneca vaccine efficacy was reduced from 66.1% to 59.8% and for the Pfizer vaccine it dropped from 93.4% to 87.9% (155). These data suggest that for the two dose vaccines, there is sufficient protection against the Delta variant for those who are fully immunized. The rapidity of the emergence and transmission of VoC underscores the importance of higher global vaccination coverage rates globally and that existing non-pharmaceutical interventions such as wearing masks and physical distancing need to continue. There is also some evidence of reduction in vaccine protection against mild–moderate symptomatic disease, but high levels of protection against severe disease and death seem to be maintained.

Should herd immunity be dismissed now, what is the role of vaccines, should we be giving booster doses of vaccines, are we likely to see more VoC and how many more? What we know is that the interplay between natural immunity, vaccine-induced immunity, and VoC is complex and we have much to learn. We know that there are individual level and population level benefits from vaccines but that the population level benefit is dependent on many factors, particularly R_0 and the extent to which infected vaccinated individuals transmit the virus. Vaccination coverage for herd immunity varies and we do not currently know what levels are needed to reach this goal. In terms of viral transmission we are seeing similar viral

loads in vaccinated and unvaccinated cases (156) [median Ct values: 21.9 (n = 80) vs. 21.5 (n = 65)]. New variants have changed the game with their higher transmissibility and/or immune escape, making reaching herd immunity much more difficult and we don't know what the next variants will look like (157).

Several rich countries, e.g. Israel, France, and Germany, are giving third–dose boosters when many poor people have not yet received their first dose of vaccine, spurring WHO to place a moratorium on boosters based on global disparity in vaccine access. We see corporate greed manifestations through vaccine manufacturing companies promoting the administration of booster doses of vaccines using arguments such as inadequate vaccine responses, waning antibody levels (homologous boosts), and variants escaping vaccine immunity need for heterologous boosts. To date, we have no correlate of immunity, nor do we know how much antibodies are required for protection. We do know from prior experience—for example, older people who had Spanish flu—that antibody levels decline over time but that memory B cells in lymph nodes can regenerate antibodies very quickly and therefore a homologous boost adds little value. Thus far, all mRNA vaccines remain effective against all current variants, displacing the argument that a heterologous vaccine boost is needed to enhance vaccine immunity against new mutated forms of the virus. There is no clinical trial evidence currently to justify booster doses. The three-dose vaccination dose schedule for persons with autoimmune disease or who are severely immunocompromised to enhance immune responses to date is the only clear justification for an additional dose of vaccination.

Finally, the hybrid immunity resulting from natural immunity with vaccine-induced immunity appears to be higher and more durable than either on its own (158) (Figure 9), providing a strong rationale for rapidly increasing vaccine coverage rates globally to limit the emergence and transmission of VoC and achieving some level of epidemic control.

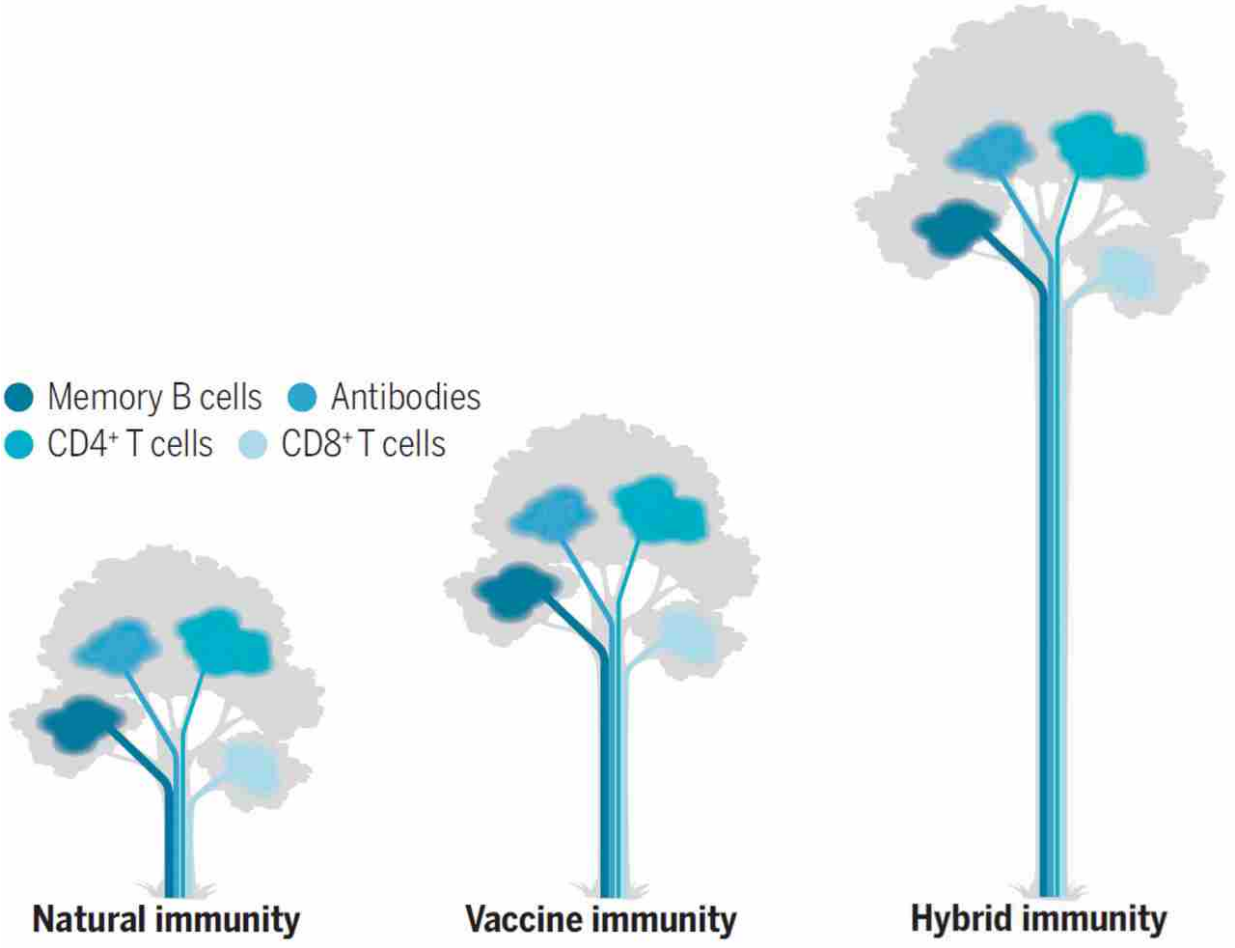

Figure 9 Hybrid immunity is much better than natural immunity.

11. Lessons learned and the way forward

The SARS-CoV-2 pandemic has affected virtually every aspect of life on Earth: physical and mental health economies, national well-being, social interactions, political fortunes, and exacerbated global, national, and local inequalities. The pandemic has underscored the importance of public health principles and applications and the interconnectedness of all persons whether in wealthy or poor countries or conditions. We know that attaining a high level of community immunity to SARS-CoV-2 will reduce the threat and spread of the infection. Due to the reluctance of many persons to get vaccinated and the failure of the world's institutions to provide vaccine equity, the pandemic continues. In rich countries where people have the

opportunity to have a vaccine some people, choose not to be vaccinated. Thus, the pandemic is now a pandemic of the unvaccinated who refuse to acknowledge their community responsibility to protect their fellow humans. Their argument that their 'human rights' are being violated ignores the human rights of their fellow humans to not be infected. Further, the human rights of people in LMICs are denied because they have not been given the chance to be vaccinated because of the system of 'intellectual property' laws which protects the profits of corporations at the expense of lives and health.

The pandemic has exacerbated existing inequalities that intersect with race, gender, and social and economic marginalization. In all countries, people living in economically deprived circumstances have been more affected by COVID-19. Crowded housing, insecure employment, care work, work in the retail and manufacturing sectors, being a migrant or Indigenous person have meant more exposure to the virus and less ability to cope with its impact. Strong healthcare delivery systems with universal health coverage and access have been shown to be most effective in protecting people from the impact of COVID-19.

The impact of the pandemic has been mitigated to some extent by our experience with the previous epidemic of HIV/AIDS, which through global solidarity ensured access to the scientific advances that has resulted in for example AIDS being transformed from an inevitably fatal condition to a chronic one. That solidarity emanated from the synergy of years of activism and advocacy from affected communities and scientists, strong public engagement and communication, and demand for accountability from politicians. Collaborations between scientists across different regions and countries resulted in the development of new methods of diagnostic testing, prevention, and treatment and infrastructure to undertake cutting edge research and clinical trials in most affected populations. The implementation of these advances strengthened health systems, improved health information systems, and enabled innovation in delivery of interventions.

The rapid pace of knowledge generation with COVID-19 was possible because of prior investments in science and technology. For example, the decades of investigations from several research centres on other coronavirus epidemics enabled an accelerated pathway to vaccine development and evaluation into the arms of people in less than a year. This unprecedented rapid response to SARS-CoV-2 needs to be applied to existing challenges and provides important lessons for confronting future pandemics.

The pandemic also demonstrated the importance of strong political leadership in ensuring that responses are guided by science, as uncertain and evolving as it may be. We have seen the dual facets of public health, namely science and social justice, become more politicised on ideological grounds by both politicians and some of the public. Public health practitioners have a responsibility to inform decision-makers, political leaders, and the public and to ensure science-based policy promulgation and implementation. Ongoing public communication and engagement has become even more important in the current era of modern formal and informal rapid communication and the rapid expansion of social media platforms. Public health must develop strategies to counter misinformation and negative messages. Parallel to the COVID-19 pandemic, a pandemic of misinformation and distrust has flourished and undermined effective responses to COVID-19.

We can be confident that there will be future pandemics, some possibly involving coronavirus, and likely other disease agents. To mutate a virus must replicate. The more people who are infected the more replications that will occur, each with a probability of mutating. Although the majority of these mutations will be non-pathogenic, some will increase their adaptability to humans and will demonstrate even greater transmissibility and pathogenicity. Thus, ongoing molecular surveillance and laboratory predictions of new and mutating agents such as Sarbecovirus is important and key for adequate pandemic preparedness and expanding the protective benefits of current vaccines.

Above all, the SARS-CoV-2 pandemic has demonstrated the complexities of disease transmission and control in a rapidly changing world. To confront the next pandemic, as well as to have a greater impact on the current pandemic it is necessary to muster all our resources: public health, political, scientific, and social, and to recognize our interconnectedness. We hope that this chapter will help understanding of and responses to the current pandemic and provide a path forward for future pandemics.

We would like to end with an exhortation from Pope Francis:

> *The pandemic has exposed the paradox that while we are more connected we are also more divided … To come out of this crisis better we have to recover the knowledge that as a people we have a shared destination. The pandemic has reminded us that no one is saved alone. What ties us to one another is what we commonly call solidarity. Solidarity is more than acts of generosity, important as they are, it is the call to embrace the reality that we are bound by bonds of reciprocity.*

1.1

The scope and concerns of public health

Roger Detels and Chorh Chuan Tan

Introduction to the scope and concerns of public health

There have been many definitions and elaborations of public health. The definition offered by the Acheson Report (Acheson 1988, p. 1) has been widely accepted:

> Public health is the science and art of preventing disease, prolonging life, and promoting health through the organized efforts of society.

This definition underscores the broad scope of public health and the fact that public health is the result of all of society's efforts viewed as a whole, rather than that of single individuals.

In 2003, Roger Detels defined the goal of public health as:

> The biologic, physical, and mental well-being of all members of society regardless of gender, wealth, ethnicity, sexual orientation, country, or political views. (cited in Detels 2009, p. 3)

This definition or goal emphasizes equity and the range of public health interests as encompassing not just the physical and biological, but also the mental well-being of society., This is in keeping with the spirit of the 1948 United Nations declaration that health is a basic human right, and the declaration of the United Nation's Millennium Development Goals. These have now been superseded by the declaration of Sustainable Development Goals (SDGs) in 2012. The 17 SDG goals focus on a broad range of topics including inequalities, poverty, climate change, and other areas essential for achieving optimal health of the public. The SDGs underscore public health as being concerned with more than mere elimination of disease, and place public health issues as a fundamental component of development.

To achieve the World Health Organization (WHO) goal of ‘health for all’, it is essential to bring to bear many diverse disciplines to the attainment of optimal health, including the physical, biological, political, and social sciences. The field of public health has adapted and applied these disciplines for elimination and control of disease, and promotion of health.

Functions of public health

Public health is concerned with the process of mobilizing local, state/provincial, national, and international resources to assure the conditions in which all people can be healthy (Detels and Breslow 2002). To successfully implement this process and to make health for all achievable, public health must perform the functions listed in Box 1.1.1.

Box 1.1.1 Functions of public health

1. Prevent disease and injuries and their negative outcomes
2. Promote healthy lifestyles and good health habits
3. Identify, measure, monitor, and anticipate community health needs (e.g. surveillance)
4. Investigate and diagnose health problems, including microbial, societal, and chemical hazards
5. Formulate, promote, and enforce essential health policies
6. Organize and ensure high-quality, cost-effective public health and healthcare services
7. Reduce health disparities and ensure access to healthcare for all
8. Promote and protect a healthy environment
9. Disseminate health information and mobilize communities to take appropriate action
10. Promote health
11. Plan and prepare for natural and man-made disasters
12. Reduce the impact of interpersonal violence and aggressive war
13. Conduct research and evaluate health-promoting/disease-preventing intervention strategies
14. Develop new methodologies for research and evaluation
15. Train and ensure a competent public health workforce
16. Continually evaluate the effectiveness of existing public health programmes

Source: data from the Office of the Director, National Public Health Performance Standards Program, *10 Essential Public Health Services*, Centers for Disease Control, 1994, available from https://www.cdc.gov/od/ocphp/nphpsp/EssentialPHServices.htm.

Public health *identifies*, *measures*, and *monitors* health needs and trends at the community, national, and global levels through surveillance of disease

and risk factor (e.g. smoking) trends. Analysis of these trends and the existence of a functioning health information system provide the essential information for predicting and anticipating future community health needs.

In order to ensure the health of the population, it is necessary to *formulate*, *promote*, and *enforce* sound health policies to prevent and control disease, and to reduce the prevalence of factors impairing the health of the community. These include policies requiring reporting of highly transmissible diseases and health threats to the community and control of environmental threats through regulation of environmental hazards (e.g. water and air quality standards and smoking). It is important to recognize that influencing politics and promoting sound health policies is an essential function of public health at the local, national, and global levels.

There are limited resources that can be devoted to public health and the assurance of high-quality health services. Thus, an essential function of public health is to effectively *prioritize*, *plan*, *manage*, *coordinate*, and *administer cost-effective health services*, and to ensure their availability to all segments of society. In every society, there are *health inequalities* that limit the ability of some members to achieve their maximum ability to function. Although these disparities primarily affect the poor, minority, rural, and remote populations and the vulnerable, they also impact on society as a whole, particularly in regard to infectious and/or transmissible diseases. Thus, there is not only an ethical imperative to reduce health disparities, but also a pragmatic imperative.

Technological advances and increasing commerce have done much to improve quality of life, but these advances have often come at a high cost to the environment. In many cities of both the developed and developing world, the poor quality of air—contaminated by industry and commerce—has affected the respiratory health of the population and has threatened to change the climate, with disastrous consequences locally and globally (Fig. 1.1.1). We have only one world. If we do not take care of it, we will ultimately have difficulty living in it. Through education of the public, formulation of sound regulations, and influencing policy, public health can contribute much to the protection and monitoring of the environment to *ensure that it is conducive for the population to live healthily*.

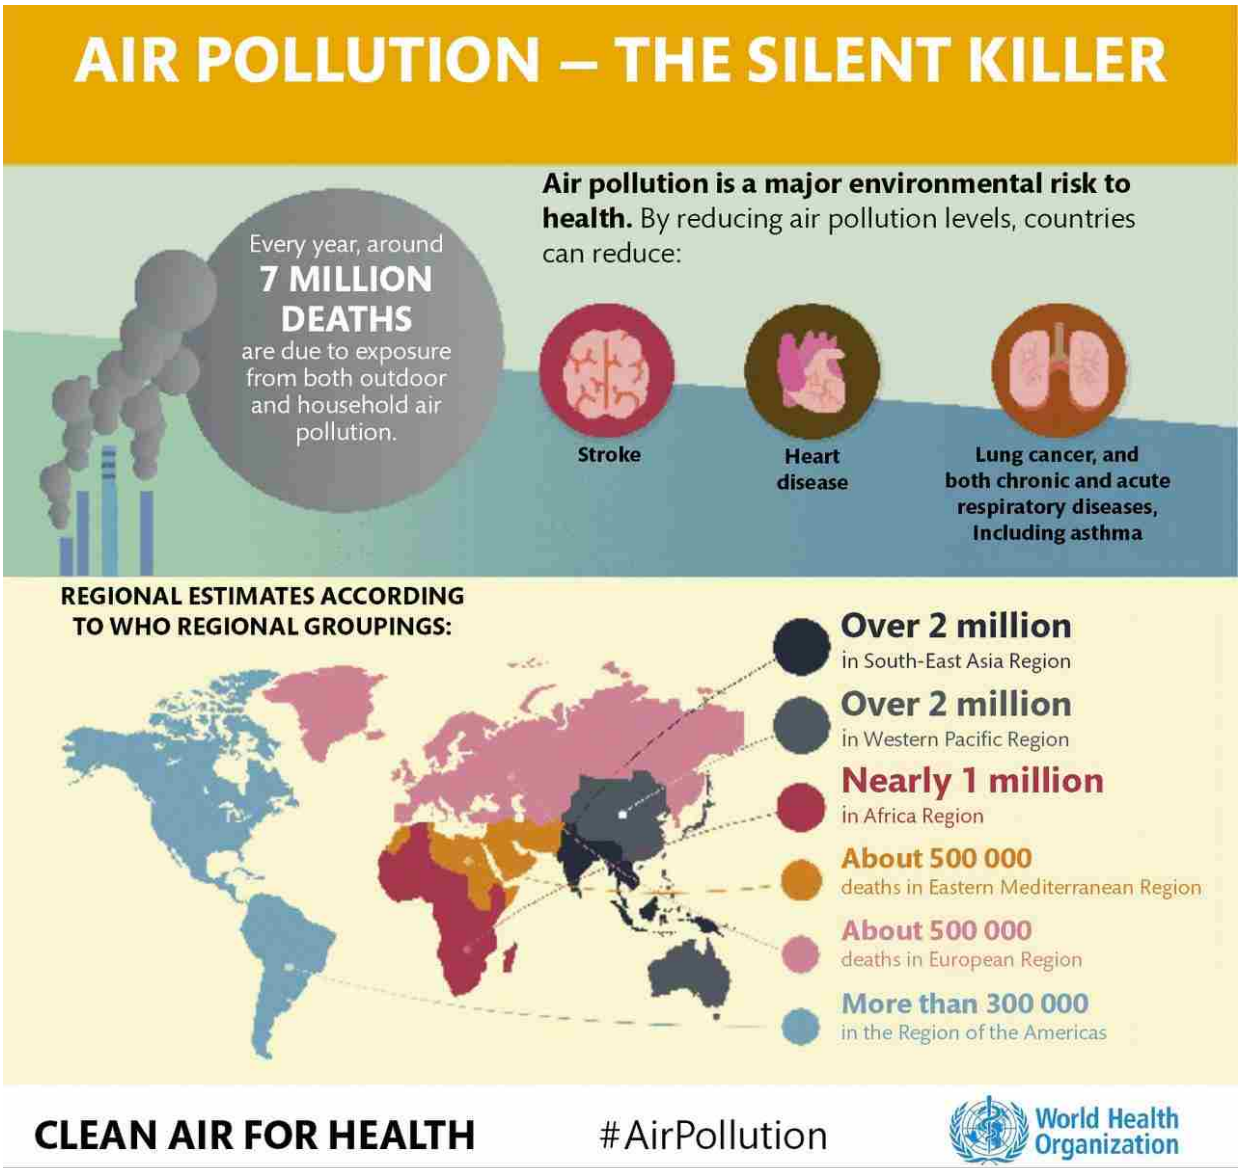

Fig. 1.1.1 Air pollution—the silent killer.
From http://www.euro.who.int/en/health-topics/environment-and-health/air-quality/news/news/2018/5/over-half-a-million-premature-deaths-annually-in-the-european-region-attributable-to-household-and-ambient-air-pollution/infographic-air-pollution-the-silent-killer

Behavioural patterns account for about 40% of all deaths in the United States, while social circumstances and environmental factors account for 15% and 5%, respectively (Schroeder 2007). To ensure that each individual in the population functions to his or her maximum capacity, public health needs to *educate the public, promote adoption of behaviours associated with good health outcomes*, and *stimulate the community* to take appropriate

actions to ensure the optimal conditions for the health of the public. This is vital since the majority of public health problems are linked to human behaviour and lifestyles. Ultimately, public health cannot succeed without the support and active involvement of the community.

We cannot predict and rarely can we prevent the occurrence of natural and man-made disasters, but we can prepare for them to ensure that the resulting damage is minimized. Thus, *disaster preparedness* is an essential component of public health, whether the disaster is an epidemic such as influenza or the occurrence of typhoons and other natural disasters.

Unfortunately, in the modern world, interpersonal *violence* and *war* have become common. In some segments of society (particularly among adolescent and young adult minority males), violence and suicide have become leading causes of death and productive years of life lost. Public health cannot ignore the fact that violence and wars are major factors dramatically reducing the quality of life for millions.

Many of the advances in public health have become possible through *research*. Research will continue to be essential for identifying and anticipating health problems and the optimal strategies for addressing them. Strategies that seem very logical may, in fact, not succeed for a variety of unforeseen reasons. Therefore, public health systems and programmes cannot be assumed to function cost-effectively without continuous monitoring and evaluation. Thus, it is essential that new public health strategies undergo rigorous evaluation before being scaled up, and once scaled up, are periodically reviewed to ensure their continuing effectiveness in diverse groups and populations.

Over the last century, the quality of research has been enhanced by the *development of new methodologies*, particularly in the fields of epidemiology, biostatistics, social, and laboratory sciences. Rapid advances in computational hardware, software, and techniques, including artificial intelligence, have greatly increased our ability to analyse massive amounts of data that incorporate thousands of variables, and to use multiple strategies to aid in the interpretation of data. It will be a major challenge to keep pace with the explosive growth in the volume and complexity of data being generated, driven by a range of factors from the pervasive use of the internet, social media, and mobile phones, to the masses of data from population studies (e.g. census), molecular biology, and whole genome sequencing studies. To glean valuable insights pertinent to public health from these huge

data sets will require new approaches, strategies, and methodologies, such as further development of machine (computer) learning techniques for finding associations with public health outcomes of relevance and discovering patterns such as geographic distributions of relevant variables within geographic subunits that can be targeted for implementation of specific interventions. The increasing use of robotics and artificial intelligence will have a huge impact on public health in the coming decades. Increasingly humans in the workforce will be replaced by robots, especially for performing dangerous and repetitive jobs. These technologic advances are likely to affect low level workers disproportionately. Thus, there will be an increasing demand for training in science, technology, engineering, and mathematics (STEM disciplines) which are essential for designing and programming of robots and other technology advances. It is essential that public health continues to use leading-edge technologies to develop more sophisticated research strategies to address current and future public health issues.

A major problem in public health has been translating research advances into effective health practice and policy in a timely manner. A recent area of research, *implementation science*, attempts to delineate barriers to and factors that facilitate rapid translation of scientific advances into improvements in health practice and development of more effective policies promoting health.

The quality of public health is dependent on the competence and vision of the public health *workforce*. Thus, it is an essential function of public health to *ensure the continuing availability of well-trained and competent professionals* at all levels, including leaders with the vision essential to ensure the continued well-being of society and the implementation of innovative, effective public health measures.

Finally, a common thread that runs through all these functions is the necessity for much greater international collaboration in data sharing, policy formulation and implementation, and management of specific public health issues. With globalization, the rapid flow of information, people, goods, and services across national boundaries means that many public health concerns and issues are interconnected in complex ways. Effective solutions will therefore often depend on joint action between different countries. In addition, now more than ever, there are many opportunities for major public health attainments to be made through cooperative action at the global level,

as has been demonstrated in the past by milestones such as the eradication of smallpox. The media can play an important role in educating the public and in facilitating public health interventions, but often must be educated about public health strategies and goals.

Contemporary health issues

Underlying the bulk of the public health problems of the world is the issue of poverty. More than half of the world's population (more than 3 billion, with one-third being children) live below the internationally defined poverty line of less than US $2.50 per day, with 1.3 billion on less than US $1.25 per day (World Bank 2012). Although the majority of the world's poor live in developing countries, there are many poor living in the wealthiest countries of the world, underscoring the disparity of wealth between the poor and the rich in all countries (United Nations Development Programme 2014). In the United States, 40.6 million Americans were living below the official poverty level in 2016. The proportion was highest among African-Americans and Hispanic-Americans (23.2%). Unfortunately, the disparity between the rich and the poor is increasing within countries (US Census Bureau 2016). Poverty causes a cascade of problems leading to poor health (Table. 1.1.1). Worldwide, 844 million people do not have access to clean drinking water, and at least 2 billion use a drinking water source contaminated with faeces, which causes diarrhoea, cholera, dysentery, typhoid, and polio (WHO Drinking Water). It is incumbent on public health to work to reduce the impact of these disparities to ensure that all members of the global society share in a healthy quality of life.

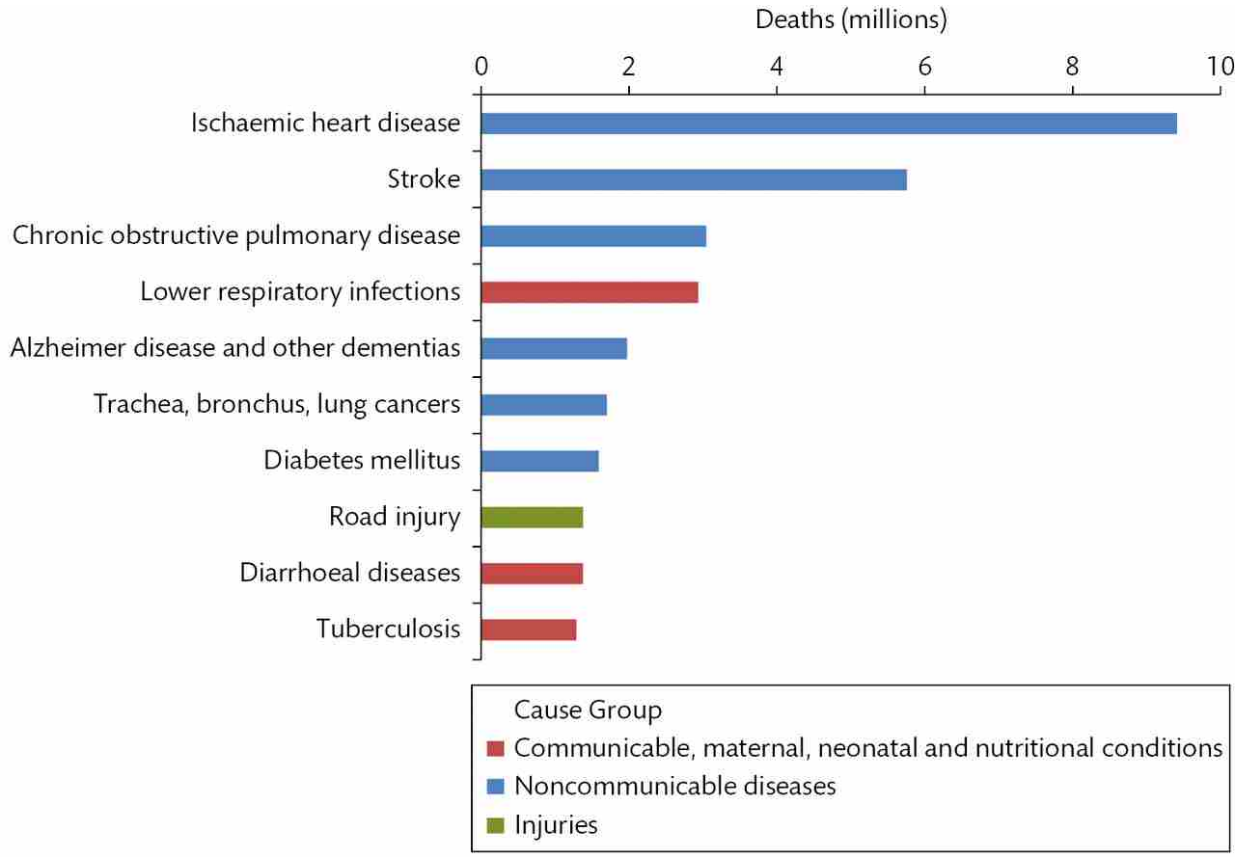
The population of the world is changing. In 2017 the global population was over 7 billion people. By 2050 it is estimated to be more than 9 billion. Population growth will be flat in many areas of the world, but in the African countries the population will continue to increase changing the relative distribution of population across the globe. Meeting these changes will be a challenge for assuring the health of the global population.

Table 1.1.1 Deaths caused by poverty-related diseases

% of deaths caused by/in	High mortality low-income countries	Low mortality low-income countries	High-income countries
Infectious and parasitic disease	34.1	24.8	2.1
Respiratory infections	9.9	8.0	3.2
Perinatal and maternal conditions	8.4	6.8	0.4
Nutritional deficiencies	1.3	1.1	0.0
Tropical diseases	0.5	0.3	0.0
Total ‘poverty-related’ diseases	54.1	40.7	6.2

Source: data from Stevens P. Diseases of poverty and the 10/90 Gap, International Policy Network, 2004.

The twentieth century witnessed the transition of major disease burdens, defined by death from infectious and/or communicable diseases, to non-communicable diseases (NCDs). In 1900, the leading causes of death in the United States and other developed countries were reported to be pneumonia and influenza. By the beginning of the twenty-first century, diseases of the heart and other chronic diseases were the leading causes of death, and pneumonia and influenza were no longer among the top ten causes of death and primarily affected the elderly (Fig. 1.1.2).



Source: Global Health Estimates 2016: Deaths by Cause, Age, Sex, by Country and by Region, 2000–2016. Geneva, World Health Organization; 2018.

Fig. 1.1.2 Top 10 global causes of deaths, 2016 (WHO Global Health Estimates).
Reproduced with permission from World Health organization. (2018) The top 10 causes of death. Copyright (c) 2017 WHO. Available at http://www.who.int/news-room/fact-sheets/detail/the-top-10-causes-of-death

The prevalence of chronic diseases will continue to increase further stressing the healthcare system. It also underscores the need for cities, which will accommodate an ever increasing proportion of the population, to innovate and adapt in order to facilitate health promotion, e.g. through providing conducive walking paths and stairs, and supporting those with reduced function and mobility or who have disabilities.

Reductions in communicable diseases were not primarily due to development of better treatments, although vaccines and antibiotics played an important role in the second half of the twentieth century. Instead, public efforts to reduce crowding and improve housing, enhancing nutrition, and providing clean water and safe disposal of wastes were key to reducing communicable diseases.

By 1980, many leading public health figures felt that infectious diseases had been eliminated as a primary concern for public health; however, the discovery and expanding pandemic of acquired immunodeficiency syndrome (AIDS) caused by the human immunodeficiency virus (HIV) in the early 1980s, and subsequently, outbreaks of the severe acute respiratory syndrome (SARS), Ebola, and Zika in the early twenty-first century underscored the fallacy of these declarations as do the persisting high rates of infectious diseases, particularly in Africa.

Although communicable diseases persist as a major public health concern, globally, NCDs have become the leading health challenge, accounting for 40 million or 71.4% of all deaths in 2016 (Fig. 1.1.3). Even in poor developing countries, NCDs are a dominant and growing concern. In 2015, 30.7 million NCD deaths occurred in low- and middle-income countries (World Health Organization 2017b). The age-standardized death rate due to NCDs among males in low- and middle-income countries was 65% higher, and among females, 85% higher than for men and women in high-income countries. This figure is particularly disturbing because low- and middle-income countries have far fewer resources and capacity to address the epidemic of NCDs. Communicable diseases, however, still accounted for almost 30% of the burden of disease worldwide, but caused a majority of deaths only in Africa. The majority of communicable diseases are now preventable through vaccines, improved sanitation, behavioural interventions, and better standards of living, although new diseases emerge that will require public health action.

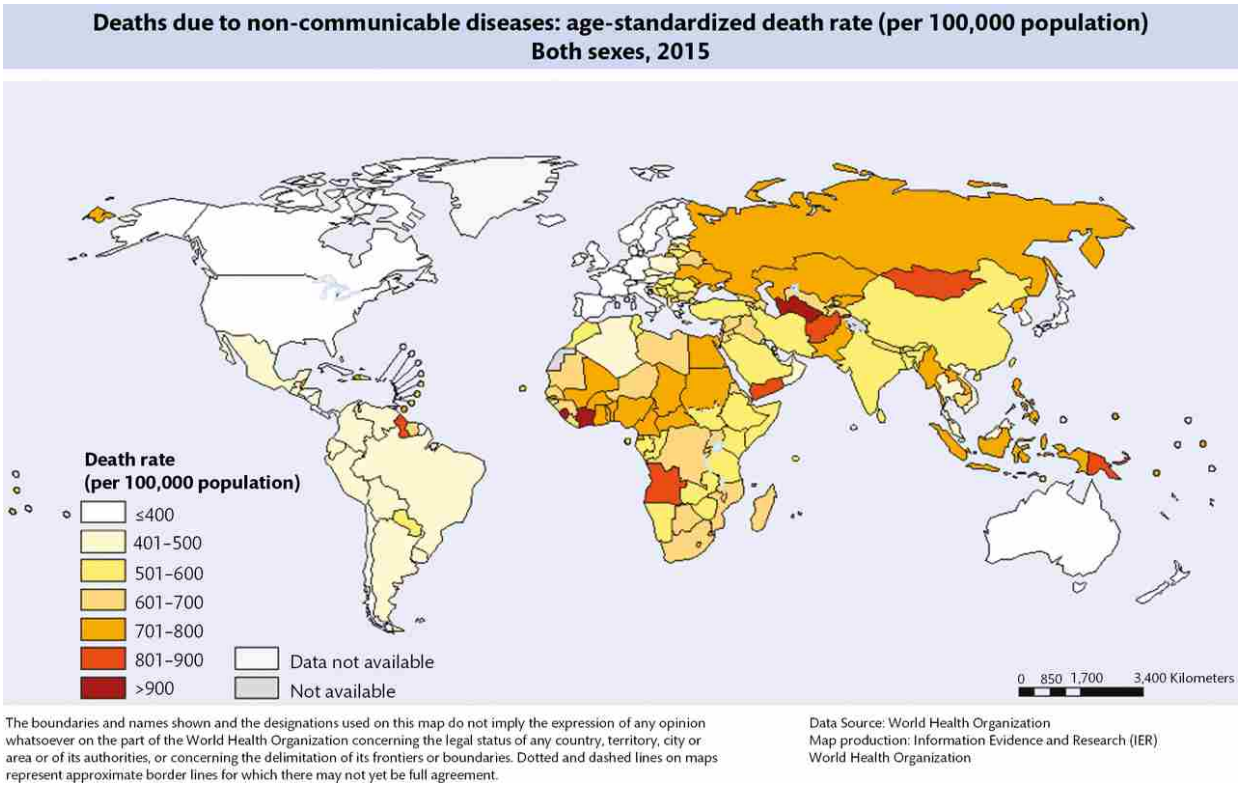


Fig. 1.1.3 Deaths due to noncommunicable diseases, 2015.

Reproduced with permission from World Health organization. (2017) Deaths due to noncommunicable diseases: age standardized death rate (per 100 000 population). Copyright (c) 2017 WHO. Available at http://gamapserver.who.int/mapLibrary/Files/Maps/Global_NCD_deaths_2015.png

Compounding the global shift to NCDs is the rapidly rising age of populations in many countries, due to increased longevity (71.4 years globally) and dramatically decreased birth rates (United Nations 2015a). Population growth is already below replacement in many countries, both developed and developing. This demographic shift to an ageing population has widespread and profound implications (Fig. 1.1.4). It will increase the burden of chronic disease in these countries, place increasing demands on healthcare and social support services, and strain public financing systems. This will occur as the proportion of the population in the productive ages decreases, which in turn will impact economic growth. The low- and middle-income countries in particular will be affected by the ageing of their populations.

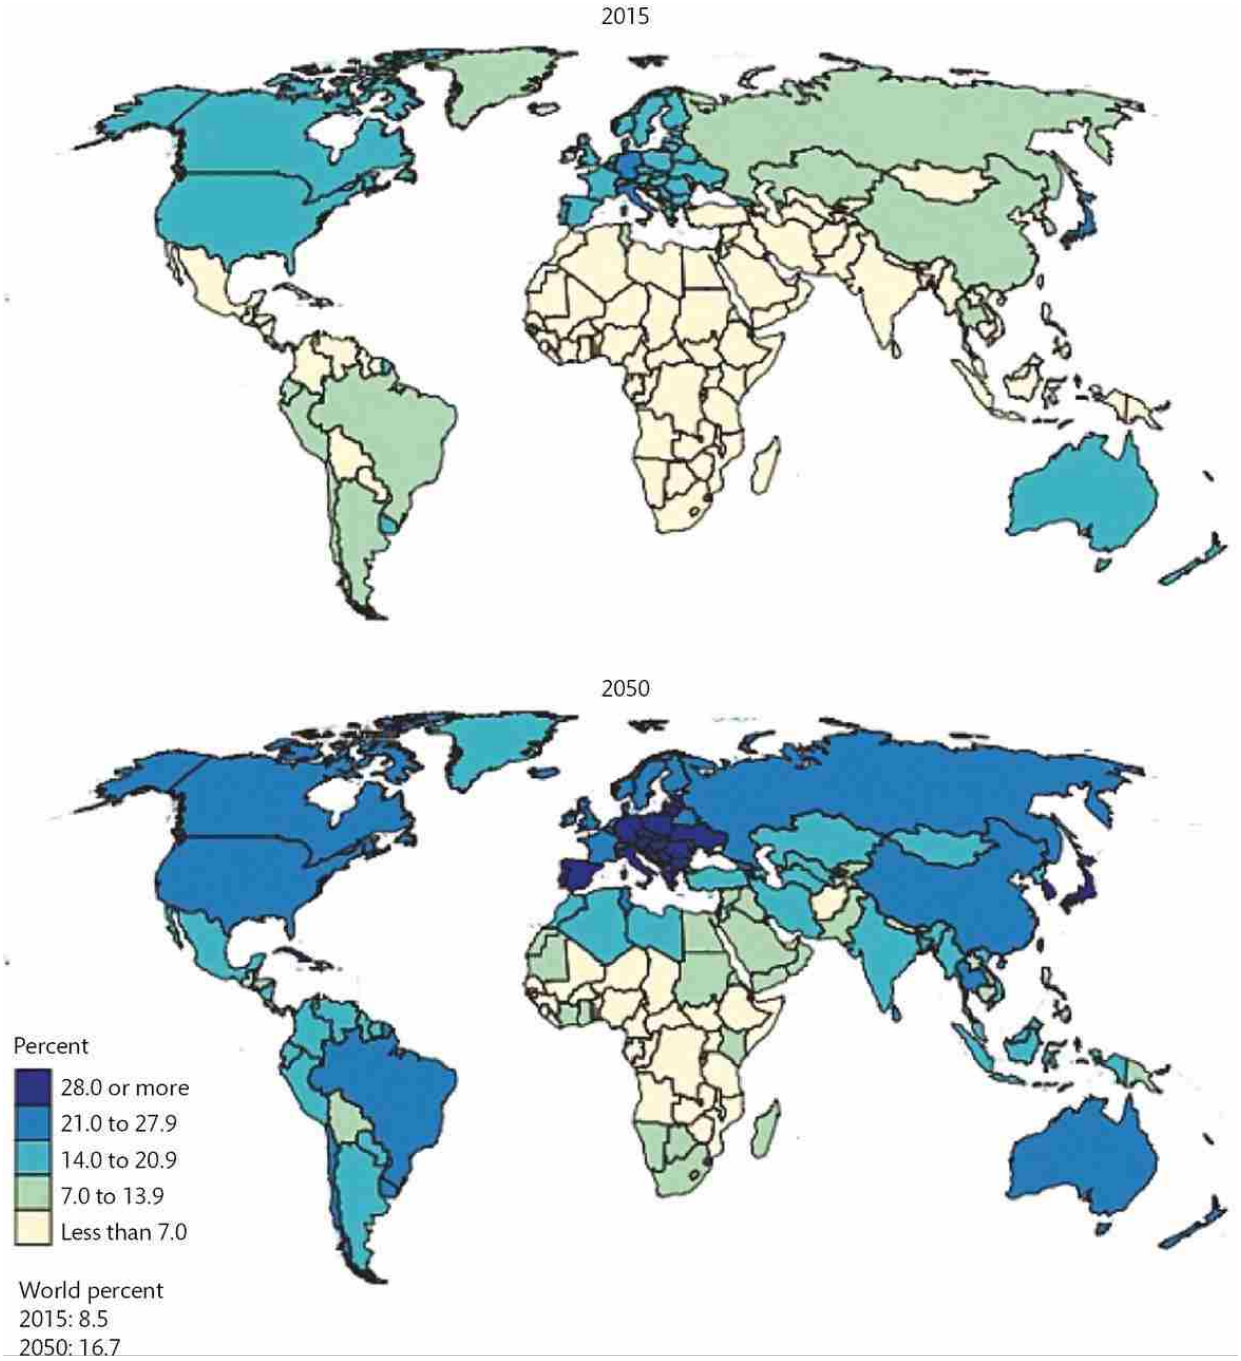

Fig. 1.1.4 Percentages of population aged 65 and over in 2015 and 2050.

Measuring disease occurrence

An essential step in defining health is to identify appropriate methods for measuring it. Traditionally, public health has defined disease in terms of mortality rates because they are relatively easy to obtain and death is indisputable. The use of mortality rates, however, places the greatest emphasis on diseases that end life, and tends to ignore those which compromise function and quality of life without causing death. Thus, the problems of mental illnesses, accidents, and disabling conditions are seriously underestimated if one uses only mortality to define them.

Two other strategies to measure health that evolved in the last half of the twentieth century have been 'years of productive life lost' (YPLL) (Lopez et al. 2007) and 'disability-adjusted life years' (DALYs) (Murray and Lopez 1997). The former emphasizes those diseases that reduce the productive lifespan (currently arbitrarily defined as 75 years), whereas the latter emphasizes those diseases that compromise function and also includes a measure of premature mortality. Using either of these alternatives to define health results in very different orderings of diseases and/or health problems as public health priorities.

Using death to identify disease priorities, the leading cause is NCDs, which account for 70% of diseases worldwide (Fig. 1.1.3). Among the chronic diseases, cardiovascular diseases account for half of the deaths. The proportion, however, varies markedly by regions of the world and level of affluence of the countries. Communicable diseases remain the major cause of death only in Africa, although they account for a significant proportion of deaths in Southeast Asia and the eastern Mediterranean. The majority of victims of these communicable diseases are infants and children under 5 years old. The persistence of communicable diseases in these areas represents a continuing major public health challenge.

DALYs and YPLL may be considered better measures of the quality of life and functioning capacity of a country than mortality (Figs. 1.1.5a, 1.1.5b, and 1.1.6). Using DALYs to establish global disease priorities emphasizes communicable diseases and injuries, which tend to disproportionately affect the young, and reduces the relative importance of cardiovascular diseases and other chronic diseases that primarily affect the elderly. The WHO has projected that the ranking of total DALYs for neuropsychiatric disorders, injuries, and non-communicable and/or chronic diseases will increase by 2020, whereas the ranking for communicable diseases will decline. Communicable diseases, which currently account for

39% of global DALYs, are expected to decline to 30% by 2030 (Mathers and Loncar 2006).

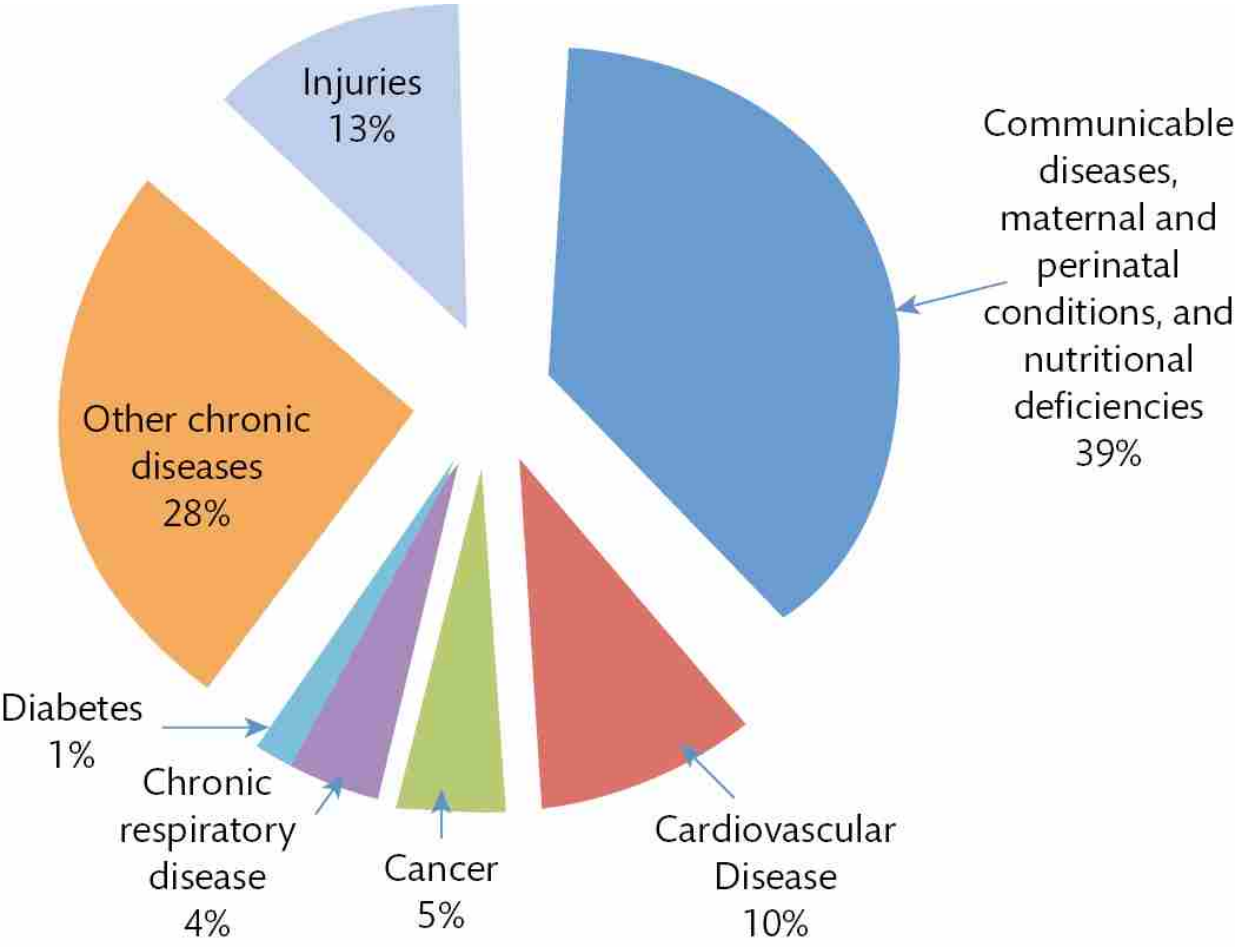

Fig. 1.1.5 Global burden: disability-adjusted life year (DALY).

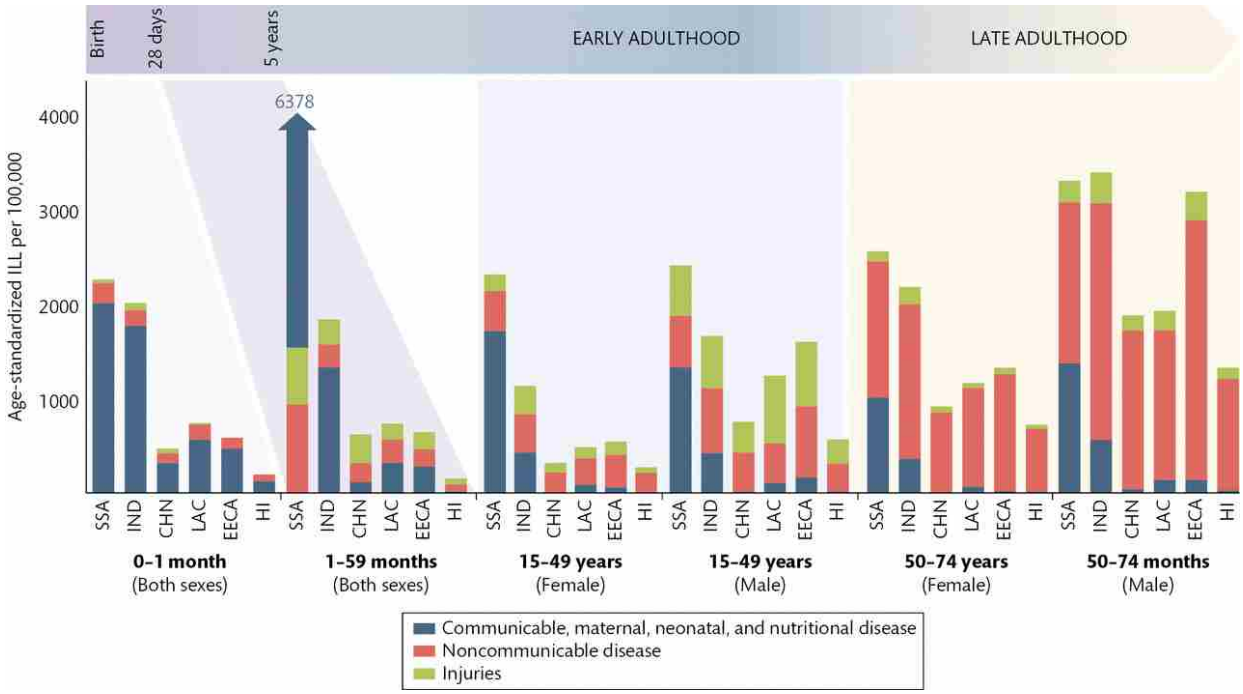

Fig. 1.1.6 YLL (potential years of life lost): estimator of the impact of premature death by world regions.
From https://libguides.acomedu.org/GlobalHealth.

According to projections by the WHO, while lower respiratory infections and diarrhoea remain the most prevalent communicable diseases, infections such as HIV, tuberculosis, and malaria will rise in terms of YPLL per 1,000 population by 2030, even as other communicable diseases will yield to intervention efforts and account for progressively fewer YPLL (World Health Organization n.d.). The YPLL per 1,000 population due to NCDs that primarily affect older people, however, is projected to remain constant, perhaps reflecting the optimism regarding the development of strategies for earlier diagnosis, better health habits, and better drugs to sustain life in patients with these conditions.

In the 1990s syndemicity introduced the concept that diseases occur in specific contexts. These include such factors as the environment (physical and social/psychologic) in which disease occur and the concept that there are interactions between diseases which affect vulnerability and severity. This theory emphasizes that disease occurs as the result of a constellation of factors, only some of which are biologic (see Fig 1.1.7). This theory, thus, suggests the need for a broader approach to public health promotion and disease intervention (Mendenhall 2017).

(editors) (2003). *Microbial Threats to Health: Emergence, Detection, and Response, Institute of Medicine, Board on Global Health, Committee on Emerging Microbial Threats to Health in the 21st Century*, Figure ES-1, p. 5, with permission from The National Academies Press.

Communicable diseases

Many new vaccines against infectious agents have been and are being developed, and many have become more affordable (Qadri et al. 2016). The WHO's regional offices working with individual countries have conducted intensive immunization programmes against the major preventable infectious diseases of childhood, but there are significant barriers to complete coverage, including poverty, geographic obstacles, low levels of education affecting willingness to accept vaccination, logistical problems, civil unrest and wars, corruption, and mistrust of governments. Poverty, weak governments, and misuse of funds have also prevented control of disease vectors that play a key role in diseases such as malaria and dengue, provision of clean water, and safe disposal of human waste, all of which are essential for control of communicable diseases.

Another major factor in the rapid spread of communicable diseases has been the rapid growth in transportation. It is now possible for an individual with a communicable disease to circumnavigate the globe while still infectious but asymptomatic. Thus, cases of SARS were reported throughout Southeast Asia and as far as Canada within weeks of the recognition of the first cases in Hong Kong (Lee 2003). Similarly, due to the extensive global food supply chains, food-borne infections can spread rapidly within and across countries.

Another source of communicable diseases is the continuing emergence of new infectious agents, many of them adapting to humans from animal sources. Box 1.1.2 lists new disease outbreaks from 1994 to 2019, including newly drug-resistant variants of new diseases and emerging infections such as MERS, Zika, and SARS-CoV2 occurring worldwide. Changes in food production, crowding of animals, mixing of live animal species in 'wet markets' (selling live animals for food) in Asia and elsewhere, and the introduction of hormones and antibiotics into animal feed have all contributed to the emergence of these new diseases.

In early January 2020 a new agent, SARS-CoV2, was recognized. The virus rapidly spread globally from China to cause a pandemic which, in the first 4 months since its identification, caused over 3.25 million cases and over 226,000 deaths severely impacting the global economy and the way society functions (Wu and McGoogan 2020; Singhal 2020). As the seventh edition of the *Oxford Textbook of Global Public Health* goes to press, many key characteristics of the virus are unknown making predictions difficult,

although it is clear that the pandemic will have a major impact on the future of the planet (Chapter 8.13).

Box 1.1.2 Newly identified infectious diseases and pathogens

Year	Disease or pathogen
2019	SARS-CoV2
2018	Acute flaccid myelitis
2012	Zika virus
2012	MERS-CoV (don’t kiss camels!)
2009	H1N1
2004	Avian influenza (human cases)
2003	SARS
1999	Nipah virus
1997	H5N1 (avian influenza A virus)
1996	New variant of Creutzfeldt–Jacob disease; Australian bat lyssavirus
1995	Human herpesvirus 8 (Kaposi’s sarcoma virus)
1994	Savia virus; Hendra virus

Source: data from workshop presentation by David Heymann, World Health Organization, 1999.

In addition to the diseases listed in Box 1.1.2, antibiotic-resistant strains of known agents have emerged rapidly due, in part, to the widespread inappropriate use of antibiotics (see also Box 1.1.3). Thus, resistant strains of gonorrhoea, *Staphylococcus*, tuberculosis, and malaria have become major problems, with the latter two being among the most important infectious disease problems globally. Development of drug-resistant malaria has been compounded by the emergence of vectors resistant to the commonly used chemical insecticides. The frightening potential for rapid and dangerous spread of antibiotic resistance through genetic elements that are transmissible between different bacterial species was highlighted by

reports of the speed and extent to which New Delhi metallo-beta-lactamase (NDM-1), which encodes multiple-antibiotic resistance, spread to many different countries (Moellering 2010).

More than one billion people, one-seventh of the world's population, suffer from one or more tropical disease, including Buruli ulcer, Chagas' disease, cholera, dengue, dracunculiasis, trypanosomiasis, leishmaniasis, leprosy, lymphatic filariasis, onchocerciasis, schistosomiasis, helminthiasis, and trachoma (World Health Organization 2015). The functional ability of those afflicted is severely compromised, in turn affecting the economic competitiveness of the poorest countries, which suffer the greatest burden of these tropical diseases. However, major strides have been achieved in reducing the burden of diseases such as leprosy, guinea worm disease, and lymphatic filariasis. Continuing efforts are needed to further reduce the impact of these and other tropical diseases.

Box 1.1.3 Factors contributing to the emergence or re-emergence of infectious diseases

1. Human ‘demographic change’ by which persons begin to live in previously uninhabited remote areas of the world and are exposed to new environmental sources of infectious agents, insects, and animals
2. People living in close proximity to domestic animals and poor animal husbandry in many parts of the developing world, leading to zoonotic infections
3. Breakdown of sanitary and other public health measures in overcrowded cities and in situations of civil unrest and war
4. Economic development and changes in the use of land, including deforestation, reforestation, and rapid urbanization
5. Climate changes causing changes in the geographic range of agents and vectors
6. Changing human behaviours, such as increased use of child-care facilities, sexual and drug-use behaviours, and patterns of outdoor recreation
7. Social inequality
8. International travel and commerce that quickly transport people and goods vast distances
9. Changes in food processing and handling, including foods prepared from many different animals and transported great distances
10. Evolution of pathogenic infectious agents by which they may infect new hosts, produce toxins, or adapt by responding to changes in the host immunity (e.g. influenza, HIV)
11. Development of resistance of infectious agents such as *Mycobacterium tuberculosis* and *Neisseria gonorrhoeae* to chemoprophylactic or chemotherapeutic drugs
12. Resistance of the vectors of vector-borne infectious diseases to pesticides
13. Immunosuppression of persons due to new medical treatments or new diseases that result in vulnerability to infectious diseases caused by agents not usually pathogenic in healthy persons (e.g. leukaemia patients, AIDS)
14. Deterioration in surveillance systems for infectious diseases, including laboratory support, to detect new or emerging disease problems at an early stage
15. Illiteracy limiting knowledge and implementation of prevention strategies
16. Lack of political will—corruption, competing priorities
17. Biowarfare/bioterrorism—an unfortunate potential source of new or emerging disease threats (e.g. anthrax)
18. War, civil unrest—creating refugees, food and housing shortages, increased density of living, etc.
19. Famine
20. Declining immunization rates (e.g. measles, mumps)

We now recognize that we will continue to see new human pathogens emerge in the future, and need to be prepared to contain them. Unless the world realizes the consequences of not protecting the environment in which we live and acts upon it, newly emerging diseases will continue to plague us.

Non-communicable diseases

With increasing control of communicable diseases and increasing lifespan, NCDs have emerged as the major global health problem in both developed

and developing countries. Even in developing countries, NCDs have assumed greater importance. The prevalence of type 2 diabetes in rural India is 7.3% (Anjana et al. 2017). Cardiovascular diseases have become a major cause of death in China. During 2000–2008, the incidence of stroke in low- and middle-income countries exceeded that in high-income countries by 20% (Feigin et al. 2009).

The causes of NCDs are many and complex. Although the immediate causes are factors such as elevated blood pressure, increased blood glucose, abnormal lipids and fat deposition, and diabetes, the underlying causes are behavioural and social. These behavioural factors include unhealthy diets that substitute pre-packaged and fast foods high in fats for a balanced diet, physical inactivity, and, especially, tobacco use; these in turn are the products of social change, including globalization, urbanization, economic improvement, and ageing. The WHO estimated that globally, insufficient physical activity contributes to 3.2 million deaths and 69 million DALYs annually (Barreto 2013), and that obesity contributes to 2.8 million deaths and 35.8 DALYs globally (World Health Organization 2017b). Some NCDs have been associated with infectious disease agents. For example, *Chlamydia pneumoniae* has been implicated in the development of atherosclerosis (Kuo and Campbell 2000), hepatitis C is a leading cause of hepatocellular (liver) cancer, and human papilloma virus (HPV) is the major cause of cervical cancer. Recently, an effective vaccine against HPV was developed that protects against cervical cancer, but it is expensive, must be administered before sexual activity begins (i.e. early adolescence) and requires multiple injections.

Fig. 1.1.8 shows the global distribution of deaths from NCDs, demonstrating the higher rates of death from NCDs in developing countries, especially in Africa. Another aspect of NCDs is the increasing survival of treated individuals who would not have survived as long previously. Many of them are left with disabilities that require modified environments to allow a reasonable quality of life and to realize their full potential in order to contribute to society. Most NCDs can be reduced by a combination of healthy behaviours, including not smoking, moderate alcohol use, and exercise (Breslow and Breslow 1993). Many developed countries have been promoting healthy lifestyles, but there is a need for greater emphasis and development of these programmes in developing countries, where the major global burden of chronic diseases exists.

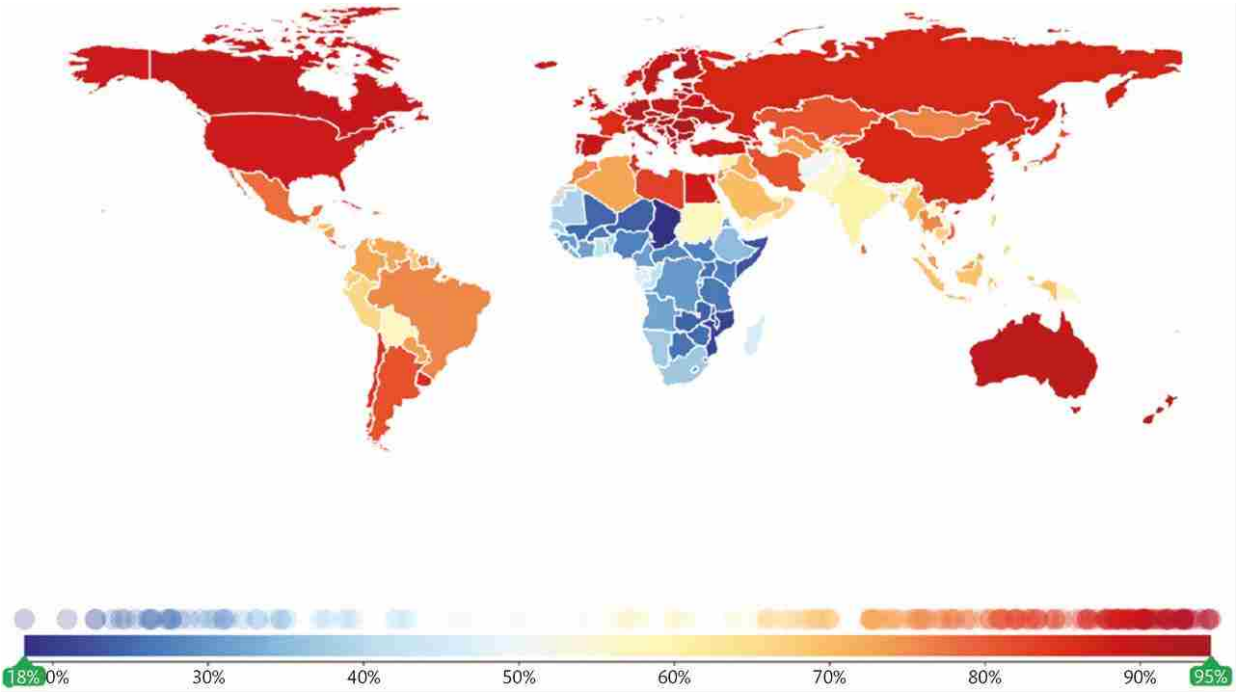

Fig. 1.1.8 Percentage of deaths from non-communicable diseases by country, 2013.
Reprinted from Mokdad A. (2016) "Global non-communicable disease prevention: Building on success by addressing an emerging health need in developing countries" *The Journal of Health Specialties* 4(20: 92–104), with permission from Wolters Kluwer: Medknow.

Mental illness

Public health professionals have only relatively recently recognized the importance of addressing the mental health needs of society on a global scale, partly due to the difficulties in defining it. It is now estimated that 1.1 billion people suffer from mental health problems, and that psychiatric disorders account for 15.5% of the global burden of disease (Collins et al. 2011) (Table 1.1.2). Mortality rates seriously underestimate the burden of mental health on society and the true extent of mental illness is probably greater.

Table 1.1.2 Global percentages of mental disorders

Disorder	Share of global population with disorder (2017) [difference across countries]	Number of people with the disorder (2017)	Share of males:females with disorder (2017)
Any mental health disorder	10.70%	792 million	9.3% males
			11.9% females
Depression	3.40%	264 million	2.7% males
	[2–6%]		4.1% females
Anxiety disorders	3.80%	284 million	2.8% males
	[2.5–7%]		4.7% females
Bipolar disorder	0.60%	46 million	0.55% males
	[0.3–1.2%]		0.65% females
Eating disorders (clinical anorexia & bulimia)	0.20%	16 million	0.13% males
	[0.1–1%]		0.29% females
Schizophrenia	0.30%	20 million	0.26% males
	[0.2–0.4%]		0.25% females
Any mental or substance use disorder	13%	970 million	12.6% males
	[11–18%]		13.3% females
Alcohol use disorder	1.40%	107 million	2% males
	[0.5–5%]		0.8% females
Drug-use disorder (excluding alcohol)	0.90%	71 million	1.3% males
	[0.4–3.5%]		0.6% females

Reprinted from Hannah Ritchie and Max Roser (2020)—'Mental Health'. Published online at OurWorldInData.org. Retrieved from: 'https://ourworldindata.org/mental-health' [Online Resource] under the CC BY 4.0 license.

Updates of global provisions for treatment of mental illness are still significantly below what is necessary to adequately address the problem.

The global median mental health expenditure per capita is US$ 2.5. Based on the WHO Global Health Expenditure database, the global median of domestic general government health expenditure per capita in 2015 was US$ 141, thus making government mental health expenditure less than 2% of global median of government health expenditure, with large variations between world regions. Levels of public expenditure on mental health are very meagre in low and middle-income countries, and more than 80% of these funds go to mental hospitals. Seventeen per cent of WHO Member States reported that persons pay mostly or entirely out of their own pockets for mental health services and 18% pay for psychotropic medicines themselves. The highest rates for out-of-own-pocket expenditures on mental health were noted in African and Southeast Asian regions. Globally, the median number of mental health workers is 9 per 100,000 population, but there is extreme variation (from below 1 in low-income countries to 72 in high-income countries) (World Health Organization 2017a). Of those with mental illness in developing countries, 76–85% do not have access to appropriate care. Although 87% of the world's governments offer some mental health services at the primary care level, 30% of them have no relevant programme and 28% have no budget specifically identified for mental health. Mental illness robs society of a significant number of potentially productive persons. With the diminishing proportion of productive people of working age and the increasing proportion of elderly dependents, it is important to assist those who are not productive because of mental illness to become healthy, productive members of society.

Population projections

Although the rate of growth of the world's population has slowed in the latter half of the twentieth century, the world's population, currently (2018) over 7.6 billion people, is still estimated to grow to 9.8 billion by 2050 (World Health Organization 2017b). An increasing proportion of the population will be mostly among the elderly and the old elderly (those over 80 years of age).

The well-being of society is dependent on the ratio of those who produce to those who are dependent. Improved technology and strategies will be required to increase worker productivity. The majority of the population growth in the coming decades will be among the old and old elderly, not

through increasing birth rates, and will result in a diminishing proportion of producers and an increasing proportion of dependents. It is expected, however, that more of the elderly will need to continue to be economically productive for longer periods of time. In 2017, the proportion of the world's population that was 60 years and older was close to 1 billion (13% of the global population and doubled since 1980), and is growing at approximately 3% each year, with the total expected to double to 2 billion by 2050 (World Population Prospects: the 2017 Revision). East Asia and the Pacific have the greatest increases in ageing populations. This will be further exacerbated because the majority of the oldest elderly will be single women who traditionally have more limited resources and lower levels of education, particularly in developing countries. The productivity and efficiency of those who produce must increase if we are to sustain and improve the quality of life for all.

The occurrence of disease in old age is directly correlated with unhealthy behaviours developed in early life. Unfortunately, concurrent with population growth, there has been a worldwide epidemic of obesity and decreased physical activity, which has increased the proportion of elderly who suffer from chronic debilitating diseases in both the developed and developing world. Thus, unless efforts to promote healthy lifestyles are successful, not only will there be an increase in the proportion of elderly, there will also be an increasing proportion of them who will require assistive care, placing a further economic and social burden on families and society.

As the population grows, there is increasing pressure to provide food, water, and other necessities to maintain a high quality of life. Shifts in dietary preferences in developing countries towards greater meat consumption also put additional strains on food production. Fertile farmlands are increasingly being converted to residential, commercial, and industrial use. Thus, more people will effectively need to be supported on less arable land. Food security will hence be a key issue for the future and this will be affected by a multitude of factors, most notably, insufficient water resources and whether there will be major increases in agricultural productivity. It is not clear how large a population planet earth can sustain.

Other public health issues

Nutrition

Appropriate nutrition is essential for health. In many developing countries (as well as among the poor and homeless in developed countries), undernutrition is a problem. Beyond access to nutritious and safe food, many of the poor have little knowledge about what constitutes a healthy diet, compounding the difficulties. At the same time, in developed and many rapidly developing countries such as China, overnutrition and obesity are a major problem underlying the current epidemic of diabetes. Industrial sectors have been more effective in promoting calorie-dense, salt-rich, and unhealthy foods than the efforts of public health professionals to champion healthy food choices consumed in reasonable quantities. This has particularly been the case for the young, and has contributed to rising childhood obesity in many countries, including the more affluent in developing countries.

Oral health

Good dental health is essential for maintaining adequate nutrition and a good quality of life. Worldwide, however, 60–90% of school children and nearly 100% of adults have dental cavities. About 30% of adults aged 65–74 years have lost all of their teeth. It was also estimated that globally, there was an average of 1.6 decayed, missing, or filled teeth among children aged 12 years old (FDI World Dental Federation, 2015). These high rates of dental problems reflect poor dental hygiene and preventive care (Pine and Harris 2007). Unfortunately, many people believe that dental care is an expendable luxury, and that visits to dentists are only necessary when there is a problem. Oral cancers are the eighth most common cause of cancer globally and the third most common in Asia. The estimated incidence, mortality and 5-year survival due to lip and, oral cavity cancer in world is 300,373 (2.1%) 145,328 (1.8%) and 702,149 (2.2%), respectively (Gupta et al. 2016). Approximately 90% of all oral cancers are squamous cell carcinomas, and the 5-year survival rate of oral cancer is estimated to be 50% globally (FDI World Dental Federation, 2015). Worldwide, approximately 450,000 new cases are found each year. Death rates are high, due to the disease usually being found in late stages (Oral Cancer Foundation). Poor dental hygiene is an important risk factor, together with smoking, as well as the habit of betel nut chewing, which is common in parts of Asia. Clearly the public health

message regarding the importance of good dental hygiene, regular brushing of teeth, and regular dental check-ups is not reaching the majority of the people.

Injuries

Injuries and violence cause about 5.8 million deaths annually (about 10% of all global deaths), nearly 1.7 times the number of fatalities that result from HIV/AIDS, tuberculosis, and malaria combined, of which about one-third are due to interpersonal violence, one-quarter to traffic accidents, and 15% to suicide. Tens of millions of people suffer non-fatal injuries that require treatment. Deaths due to injuries are almost three times greater in developing than in developed countries. Furthermore, they occur more commonly among younger persons and children; for those aged 5–44 years, injuries are the third leading cause of death (World Health Organization 2014a). Injuries can be broadly categorized into the following groups: motor vehicle accidents, suicide, homicide, and unintentional injuries, including occupational injuries and falls. Motor vehicle accidents account for the largest proportion of deaths due to injury (23%; over 3,400 deaths each day), and tens of millions of people are injured or disabled every year (World Health Organization 2014b). Falls, particularly among the elderly, are also a major cause of DALYs.

Unintentional injuries are largely preventable through community and governmental intervention. Thus, improved roads, separation of different modes of transportation, enactment, and enforcement of seat belt and helmet laws, implementation, and enforcement of safe practices at work, and improved designs of houses, automobiles, ladders, and other equipment and tools have all been shown to significantly reduce injuries and deaths due to accidents.

Homicide, violence, and suicide

Homicide, violence, and suicide represent a growing problem, particularly among the young. Homicide and suicide are among the leading causes of death globally. In some minority groups in the United States, homicide and violence are the leading cause of death of youth, followed by suicide. Globally, approximately 30% of women have experienced physical and/or

sexual violence from their intimate partners (World Health Organization 2014d). In China, suicide remains the leading cause of death among women in rural areas. Globally, the WHO predicts that homicide and suicide will account for an increasing proportion of deaths.

Vulnerable populations

Public health has always been concerned with the health and well-being of vulnerable groups who require special attention. The definition of a vulnerable population varies by time, situation, and culture, but the common characteristic across all vulnerable groups is their special susceptibility to poor health and quality of life. The list of vulnerable groups includes the poor, minorities, women, children, the elderly, the handicapped, the illiterate, orphans and street children, immigrants, rural-to-urban migrants, refugees and displaced people, the homeless, and the mentally ill. In certain situations, other groups may be considered vulnerable. For example, in the face of epidemics such as HIV/AIDS, one should also consider adolescents to be a vulnerable group. Often vulnerable individuals live at the margins of society and have difficulty accomplishing the basic functions of living and accessing healthcare. Thus, they require assistance. In many societies, particularly in developing countries, the family acts as the safety net for these groups, but if the family itself is vulnerable or dysfunctional, this safety net is compromised. Societies with sufficient resources have developed social support programmes that assist the vulnerable, but these programmes seldom cover the full range of vulnerable groups, and may not adequately support those whom they target. Universal access to healthcare is one component of assisting the vulnerable, but presently, even in wealthy developed countries such as the United States, healthcare is not available to all, and strategies to fund universal healthcare are difficult to implement.

In almost every country, developed and developing, there are homeless people, many of whom suffer from multiple problems, including mental illness. The ability to function adequately and achieve good health among many vulnerable groups, including the homeless, mentally ill, alcoholics, and drug addicts, is adversely impacted by additional factors such as poverty, prejudice, and stigmatization by society. The US is experiencing an epidemic of overuse of opioid drugs, due to overprescribing. Thus, programmes to assist the vulnerable need to also encourage society to take

supportive action in order to be optimally effective. This is a particular challenge in respect to persons with handicaps. Many developed countries have provisions for persons with handicaps, but in poorer countries, those with handicaps face substantial difficulties to function in society, and many do not survive.

Over the last decade our understanding of the diversity of society has increased as we have recognized, for example, that gender encompasses more than the dichotomy of male and female and is actually a spectrum of sexual orientations and behaviours. Traditionally society has either ignored or ostracized groups that deviate from the 'norm'. In order to achieve true equity it is incumbent on public health to champion diversity and equality as we recognize more diverse subgroups in our society.

In designing programmes for vulnerable groups, a further complication is the fact that the specific problems and needs of each of these groups differ, and they thus require public health actions which are tailored to their requirements. For some of these groups, such as mothers and children and the handicapped, there are well-established programmes, although coverage is far from complete and the quality of these programmes varies widely. For others, such as illiterate persons and migrants, there are fewer established programmes. If we are to meet the public health goal of 'health for all', we need to identify and assist the vulnerable groups within societies to achieve their maximum possible health and function.

The environment

> Environmental health comprises those aspects of human health, including quality of life, that are determined by physical, chemical, biological, social, and psychosocial processes in the environment.
>
> *Draft definition developed at a WHO consultation in Sofia, Bulgaria, 1993* (WHO Regional Office for Europe 1994)

Currently, one of the major problems that the world faces is deterioration of the environment caused by the increasing numbers of people and the accumulation of wastes produced by them, their vehicles, and the industries they support. Thus, the quality of the air that we breathe has declined, especially in developing countries where rapid economic growth has been achieved at the expense of the environment (Table. 1.1.3). The most polluted cities of the world are concentrated in developing countries, which often

have the least capacity and political will to reduce pollutant levels. Pollution of the world's oceans, which receive massive amounts of biological and chemical wastes daily, affects not only the quality of the water, but also the ability of the ocean to sustain marine life, an important source of food.

The number of known chemicals globally exceeds 14 million, of which over 60,000 are commonly used. All of these ultimately end up in the environment. They are the result of the huge proliferation of industry, technology, and automobiles in the twentieth century. The full health effects of many of these chemicals are still unclear and difficult to establish. Twenty-three per cent (23%) of all deaths globally are attributable to the environment (approximately 12.6 million deaths annually) (WHO Environmental Impacts on Health). As the twenty-first century progresses, the number of pollutants will continue to increase. Exposure to ambient $PM_{2.5}$ (particles with diameters of less than 2.5 microns) was ranked fifth of all global risk factors in 2014. It is estimated that it caused 4.2 deaths and 103 million DALYs globally (4.2%) in 2015, with attributable deaths increasing from 3.5 million in 1990 to 4.2 million in 2015 (Cohen et al. 2017).

Problems of the environment occur at the personal level (at home and the workplace), the community level (e.g. air and water pollution), and globally (e.g. global warming, hazardous and radioactive waste). Although these problems may be viewed separately, they are in fact all global issues affecting both local and remote populations. Thus, slash-and-burn agricultural practices in Indonesia result in periodic and sometimes severe air pollution problems in neighbouring Singapore and Malaysia. Industrial pollutants released in the industrial states of northeastern United States cause acid rain, which adversely affects crops and people in the midwestern United States and southern Canada. Pollution of rivers upstream can adversely affect communities and countries downstream, as happened in 2005 when nitrobenzene was released into the Songhua River in Heilongjiang, China, contaminating drinking water downriver in both China and Siberia, Russia.

Air pollution

The rapid increase in automobiles and industry has caused widespread air pollution in most urban areas of the world, with the worst occurring in the developing countries that have rapidly industrialized at the expense of their environment (Table. 1.1.3). The main pollutants are ozone, particulate matter, carbon monoxide, nitrogen oxides, sulphur dioxide, and lead. Now,

in the early part of the twenty-first century, many of these countries are realizing the need to protect the environment. Unfortunately, reversal of decades of pollution is far more difficult and costly than prevention.

Table 1.1.3 Global estimates of comparative occupational accidents and work-related illnesses by world region and sector categories

Region	Fatality rates of each economic sector					
	Agriculture		Industry		Service	
	2010	2014	2010	2014	2010	2014
HIGH	7.8	no change	3.8	no change	1.5	no change

The harmful effects of air pollution extend beyond the environment. Many members of society, including asthmatics and persons with chronic respiratory disease, are vulnerable to even relatively low levels of pollutants. Levels of pollutants observed in many developing countries, especially in China and India, are considerably higher than in developed countries. A

study carried out in China in 2015 (Levin 2015) estimated that 1.6 million deaths per year in China are attributable to air pollution, and cancer rates have increased dramatically (as much as fourfold in industrial provinces), with an estimated 4 million cases in 2015 that resulted in nearly 3 million deaths (Carney 2016). However, the true cost of uncontrolled industrialization and pollution in these countries is not fully known.

Indoor pollution is a particular problem in developing countries, where cooking is typically fuelled by coal or charcoal fires in poorly ventilated houses. However, it is also a problem in wealthier countries in which harmful chemicals are used for cleaning and household construction.

Water pollution

The main types of water pollutants are mercury, nitrates, phosphorous, faecal coliform, and bacterial pollution. Those who live in developed countries take the provision of safe drinking water for granted, but 40% of the world's population does not have access to clean drinking water, a basic necessity of life. As the world population expands, production of waste increases, and the problem of protecting water supplies also rises. Approximately 60% of the world does not have adequate facilities for waste disposal. Even in leading cities in developed countries, pollution of the water supply can occur. The increased rate of upper respiratory infections and gastrointestinal disorders among surfers and others using the ocean for recreational purposes has been well documented. Beaches in most urban areas are frequently closed when the sewage disposal systems that drain into the vicinity become overwhelmed. Acid rain from industrialization has caused acidification of lakes, making them inhospitable for fish and other marine life, thus compromising the food supply. Recently there has been discussion about whether the benefits of omega-3 fatty acids found in fish outweigh the risk of mercury poisoning among those who eat large quantities of fish. Ensuring a safe adequate water supply for people in both developed and developing countries must remain a public health priority.

Other pollutants

The most common types of soil pollutants are heavy metals such as cadmium, chromium, copper, zinc, mercury, pesticides or herbicides, organic chemicals, oils and tars, explosive or toxic gases, combustible or radioactive

materials, biologically active compounds, and asbestos; these pollutants can enter the soil through poor agricultural practices, industrial runoff, mining, landfill leakage, littering, or the improper or illegal dumping of household or industrial waste materials. As the population of the world rapidly increases and technology produces new substances and processes, not only the amounts of pollutants, but also increased varieties of pollutants. As new substances are developed, it would be ideal if their use was not permitted until plans and provisions are developed and implemented for their safe disposal. However, this is often not the case in practice.

Biodegradable pollutants have a limited lifespan in the environment, but there is increasing production of non-biodegradable substances such as plastics, which are now ubiquitous, and hazardous materials such as radioactive wastes that persist for generations. The problem of discarding these materials safely has become a major public health issue. In some cases, developed countries are paying developing countries to accept their hazardous waste products. This strategy does not solve the problem, but shifts it to those countries that have fewer resources with which to deal with the challenge, and which are increasingly reluctant to accept wealthy countries' garbage.

In the past decade, nanoparticles (1 nanometre is 1 billionth of a metre) have been increasingly used in the production of foods, drugs, cosmetics, and other products used by humans. Particles of this small size become reactive in the body and, according to reports (Li et al. 2009), can cause serious damage to lung, liver, and brain cells. Given this problem, it is important that the use of nanoparticles in products intended for human use be regulated.

Climate change

One of the most serious, long-term challenges of the twenty-first century is global warming due to the release of carbon dioxide and other 'greenhouse gases'. Climate changes affect the social and environmental determinants of health, including safe homes, clean air, safe drinking water, sufficient food, and safe homes. Climate change may affect health through multiple ways, such as increased frequency and intensity of heat waves, reduction in cold-related deaths, increased natural disasters such as floods and droughts, changes in the distribution of vector-borne diseases, and effects on the risk of disasters and malnutrition. There is growing evidence that the

consequential climate change will be associated with increased public health risks such as heat-related disorders, infectious diseases, respiratory and allergic disorders, malnutrition, mental health problems, and violence (Patz et al. 2005).

A major review by WHO to assess the public health impact of anthropogenic climate change to date, estimated that from the mid-1970s, climate change might already have contributed to 150,000 deaths and about 5 million DALYs per year. These are largely related to increased incidence of conditions such as malnutrition, diarrhoea, and malaria (World Health Organization 2014c). Mitigating the health impact of global warming and climate change at the regional level is a major public health issue for this century, which unfortunately has been politicized.

Rescuing the environment

To prevent further degradation of the environment and to tackle the threat of global climate change, strong political will is required of the countries of the world. For example, while the United States is one of the world's major producers of carbon dioxide and other greenhouse gases, in 2017, President Trump refused to endorse the Paris Accord on Climate Change, an international treaty aimed at stabilizing global greenhouse gases at levels that would avoid dangerous climate change.

From a public health perspective, it is unrealistic to expect that the risks from environmental pollution and hazardous waste can be reduced to zero. Instead, the concept of 'acceptable risk' will continue to be a part of the process. Determining the level of acceptable risk will probably be arrived at through an interplay of the scientific data and evidence, with policy and political considerations. Public health professionals and researchers must play a strong role in these determinations.

Occupational health

> Occupational diseases are different from other diseases, not biologically, but socially.
>
> Henry Sigerist, 1958 (Sigerist 1958–1961)

The International Labour Organization's Health and Safety Programme estimated that each year globally there are over 2 million work-related

deaths, over 300 million suffering from work-related diseases, and approximately 3.7 million fatal and non-fatal work-related injuries. In some developing countries, child labour is still the norm. Twelve million serious injuries occurred among young workers in 2011. This affects more people than those who have myocardial infarcts (heart attacks), strokes, or newly diagnosed malignancies annually. A significant proportion of these deaths and injuries are preventable by improving safety in the workplace. However, safeguarding the health of the worker often receives less priority than the need to produce goods cheaply, especially in developing countries, despite the increase in workplace fatalities in low- and middle-income countries in four of the six WHO regions (Hamalainen et al. 2017) (Table 1.1.3).

The nature of the workplace is constantly changing, with increasing proportions of workers being involved in service industries rather than in manufacturing. Over the last decade particularly, production of goods has shifted rapidly to developing countries, where labour costs are lower. The manufacturing industries in these countries are often subject to fewer and less comprehensive safety regulations, and in some cases, are associated with low salaries and few or low healthcare benefit provisions for workers, especially for migrant workers from rural areas. Increasingly, women are entering the workforce and must manage both work and family. Larger numbers of workers are being employed on an informal part-time basis. While this reduces labour costs for industry, these informal part-time workers do not usually receive work-related benefits such as retirement and health insurance. They now represent 50% or more of the workforce globally. This segment of the workforce is particularly vulnerable to injury and limited access to healthcare.

As noted earlier, the population is ageing, and the proportion of the population that is economically active is diminishing. In response to this change, the age of eligibility for social security benefits in the United States is increasing, and mandatory retirement is being phased out. It is now projected that the proportion of workers over the age of 60 will increase to 20% in Japan and 10% in the United States by 2030 (Population Projections 2000). The United Nations report on World Population Ageing 2015 noted that among individuals aged 65 years or over, 30% of men and 15% of women were active in the labour force (United Nations 2015b). The needs of older workers are different and greater than those of younger workers. Thus, the changing nature of the workforce will require corresponding changes in

work safety regulations and health benefits to ensure a healthy, productive workforce.

Provision of and access to healthcare

Access to preventive and curative care is a requirement for health in every society, whether rich or poor. Access to affordable healthcare has long been a problem for the poor and for rural residents, especially in developing countries. Even in the United States, full access to healthcare remains a problem. Health insurance is prohibitively expensive and beyond the reach of many in the middle classes, unless it is subsidized by employers or government. Increasingly, employers are attempting to free themselves from the cost of health insurance for their employees through a variety of strategies. The elderly also have problems with healthcare; because healthcare utilization and costs tend to increase with age, insurance companies have been less willing to cover the elderly, and many governments, even in developed countries, do not provide adequate support for the elderly. The Affordable Care Act enacted under President Obama extended coverage significantly, but President Trump and the Republican Congress have undermined it, causing 13 million Americans to lose their coverage. In developing countries, the rural poor are particularly at risk. Few health professionals are willing to work in rural areas, and the cost of providing care in less populated areas, even in wealthier countries, is greater than in urban areas. Innovative strategies are needed to promote universal coverage and ensure that the rural poor and elderly have access to reasonable healthcare.

Bioterrorism and war

The history of use of biological weapons in war extends back for hundreds of years. In the Middle Ages, corpses of plague victims were catapulted into castles under siege. In more modern times, anthrax was used to contaminate the US postal system, resulting in several deaths. The WHO and public health agencies of individual countries have developed plans to quickly diagnose and control bioterrorist incidents. However, these threats to the

health of the public will continue until the underlying causes of terrorism and bioterrorism are addressed.

Few actions can have the magnitude of negative impact on the health of the public that war has. Men, women, and children are killed, children are forced to serve as soldiers, homes are destroyed, major segments of the population become displaced refugees, women are raped, and the social and/or economic fabric of the countries involved is destroyed. Recovery usually takes years to decades. The outside world, particularly those countries adjacent to warring nations, must cope with the huge influx of displaced persons, and action needs to be implemented to help those still in the country suffering from the impact of the war. The consequences of war are so severe and wide-ranging that it is imperative that better ways be reached to resolve international conflicts. The resources ploughed into armed conflict could be better deployed on humanitarian and public health support.

Ethics in public health

Although ethical issues are implicit in the delivery of public health, it was only after the Second World War and the recognition that ‘scientific experiments’ in Nazi Germany violated human rights that an emphasis was placed on recognizing the ethics of public health actions, particularly research. The Declaration of Helsinki (World Medical Association 2002), the Belmont Report (US National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research 1979), and the Council for International Organizations of Medical Science (2002) have promulgated ethical guidelines for research and the establishment of institutional review boards worldwide to ensure that medical and/or public health research is conducted ethically and does not violate human rights. However, there are inherent ethical conflicts in many public health actions. For example, some consider that the human rights of ‘typhoid Mary’, a typhoid carrier who insisted on working as a cook in the early twentieth century, were violated when she was incarcerated to prevent her from continuing to prepare food that initiated typhoid epidemics. Protecting the human rights of a man to refuse testing for HIV may result in him unknowingly infecting his wife, yet-to-be-born children, and other sexual contacts. By protecting his human rights, the human rights of his wife or partner and future family will be violated, underscoring the complexity of human rights issues.

Implementing public health programmes and research often results in ethical conflicts and the need to balance the good of society against potential harm to the individual. It is imperative to inform society, particularly those who will be involved in the public health programmes or research, about the nature of the ethical conflicts inherent in action. For example, a trial evaluating the effectiveness of prophylactic treatment to prevent HIV infection in sex workers in Cambodia was stopped by the prime minister, who felt that the prevention trial exploited Cambodian sex workers. A more intense effort on the part of the researchers to inform the public and politicians about the nature of the study and the potential benefit to sex workers, not only in Cambodia, but globally, might have averted this unfortunate outcome.

Public health interventions

One important task of public health professionals is to raise the level of anxiety of the public about public health problems to the level at which they will be willing to take an appropriate action. In this, an appropriate balance must be struck, since raising the level of anxiety too little will result in inadequate or no action, while raising it too high may promote a fatalistic attitude and, as in the case of the HIV/AIDS epidemic, may promote stigmatization and isolation of affected individuals, seriously complicating the task of intervention. The difficulty for the public health professional is creating the level of anxiety that results in the required action while minimizing unintended consequences.

Public health interventions can be divided into four categories: social/biological/environmental, behavioural, political, and structural. The public health professional must use strategies in all four categories to achieve the maximum health of the public.

Social, biological, and/or environmental interventions

The strategy that has had the greatest impact on improving the health of the public has been an improved standard of living, including provision of clean water and safe disposal of wastes. Unfortunately, these interventions have not reached much of the world where crowding, unsafe and insufficient

water, accumulation of wastes, inadequate housing, and lack of economic development persist.

The most cost-effective biological intervention strategy is immunization, in part because it requires minimal behavioural change and usually involves only a single series of actions. The WHO has taken the lead in promoting vaccine coverage worldwide through its Expanded Programme on Immunization. The appropriate use of vaccines has reduced the majority of childhood infections in developed countries, and significantly reduced them in most developing countries. Smallpox, a major infectious disease problem until the latter half of the twentieth century, has now been eliminated. The WHO has now targeted polio, but more challenges, such as hepatitis, tuberculosis, and measles, remain. However, it is important to realize that development and production of a vaccine is only the first step. An effective vaccine against smallpox was available for over 150 years before smallpox was eliminated. The key was the strategy of vaccine coverage, ‘search and contain’, together with adequate political will and funding that permitted global elimination of that disease. Thus, the strategy for utilizing the vaccine is perhaps equally important as the efficacy of the vaccine itself. Public education and engagement must continue to be a major priority. Recently, attacks from the media, particularly social media, have caused acceptance of vaccines to decline, reducing the level of ‘herd immunity’ required to prevent epidemics (Karlamangla 2018).

Another biological strategy is to eliminate the vectors of disease, the major approach currently in use for the control of dengue, arboviral diseases, and many of the parasitic diseases. However, overzealous use of pesticides can also create problems. For example, dichloro-diphenyl-trichloroethane (DDT), used widely in the twentieth century as an insecticide, still contaminates the food supply, creating other health problems, including the risk of malignancy.

Treatment can also be considered a biological intervention strategy. To confront tuberculosis, one of the major infectious diseases of the twenty-first century, directly observed treatment short course (DOTS) has been successfully implemented in countries where the disease persists, and reduces transmission and development of multidrug-resistant tuberculosis (TB). Treatment of sexually transmitted infections and contacts to reduce the reservoir of infectious people is a major strategy for control of transmission,

but has yet to prove effective in stopping the current epidemic. ‘Treatment as prevention’ has become a mantra of HIV/AIDS control.

Behavioural interventions

Most public health interventions depend ultimately on behaviour change, whether it is personal or community behaviour. At the personal or individual level, promotion of good health habits, including avoidance of smoking and excessive alcohol use and other dependency disorders are important interventions that have a major impact on health. At the community level, confronting attitudes towards acceptable sexual behaviour and persons with dependency disorders and stigmatizing diseases are key to establishing community ‘norms’ that promote a healthy lifestyle and include all segments of society. However, modifying individual behaviour and community norms is difficult, and it is even more difficult to ensure persistence of the modified behaviour. However, the majority of the public health interventions will not be successful unless they are embraced and sustained by the community at the individual, local, national, and international levels, and accompanied by appropriate regulations and policies. The success of the antismoking campaigns in the United States and Britain and population control in China (the one-child policy) affirm that it is possible to change community norms.

Many theories identifying strategies to modify behaviour have been proposed. One of the most interesting is the Popular Opinion Leader model (Kelly 2004), which utilizes the natural leaders found in any social group as agents of change. In the United States, this strategy has been demonstrated to change behaviour in groups of men who have sex with men, and has been evaluated in other populations worldwide (Rotheram-Borus et al. 2011). Ultimately, if public health interventions are to be effective, they must be adopted by the community. The media can play an important role in facilitating these interventions and assuring that they become community norms.

Political interventions

Public health *is* politics. Any process that involves obtaining the support of the public will involve politics and differing points of view. For example, the campaign to stop smoking was strongly opposed by the tobacco industry,

which spent millions of dollars trying to counter the many reports on the adverse health effects of smoking. Countering the efforts of the tobacco industry required obtaining the political support of the public in order to pass laws and regulations limiting smoking, placing health warnings on cigarette packages, and raising taxes on cigarettes. Many needed regulations transcend boundaries and require international cooperation (e.g. regulation of greenhouse gases).

If we are to succeed in safeguarding the oceans, inland waters, and the air we breathe, it will be through political process requiring global coordination and joint action. This process has already begun in many developed countries, which have passed strong laws regulating emissions from automobiles and factories, although they are constantly under attack. Now this process must be expanded to the developing countries, where the worst pollution is currently occurring.

One of the most urgent issues before the public today is the battle over emission of 'greenhouse gases', which are causing a rise in temperatures globally. This temperature rise will adversely affect the quality of life of our children, grandchildren, and their grandchildren. Unfortunately there is still political action in the US to not take the necessary steps to arrest or reverse this detrimental warming trend.

It is important that the political process puts in place measures to improve the health of the public, based on sound scientific evidence. Pushing agendas not based on sound scientific evidence will undermine the credibility of public health professionals and our ability to accomplish our legitimate goals. Obtaining this evidence is not always easy. For example, accumulating evidence on the long term (induction period of years to decades) impact of adverse exposures is not easily established, and often requires extrapolation from data from the impact of acute high-dose exposures to lower long-term doses. This often requires relying on models that are difficult for the public to understand, and are often subject to debate, even within the scientific community.

Structural interventions

An important end-point of the political process is the passage of laws and regulations. This action, if implemented, can have a very significant impact on the improvement of the health of the public. The passage and

enforcement of helmet laws for motorcycles in Indonesia, the US, and Vietnam reduced the incidence of associated brain injuries and deaths. The incidence of lung cancer and heart disease among men has been significantly reduced, partly due to the laws regulating smoking in public spaces and the high taxes imposed on cigarettes. In 2013, China began very strong antipollution measures, particularly to stop use of coal, and the air quality in China has now greatly improved (Economist 2018). Many of the current public health problems of the world, particularly those involving protection of the environment, can best be addressed through structural changes requiring passage and implementation of laws and regulations. To accomplish this will require changing the attitudes and behaviour of the public and ensuring that public health regulations and laws are enforced.

Private support of public health

Private support has played an important role in the development of public health, especially in the twentieth century. The Rockefeller Foundation supported the first school of public health in the United States at Johns Hopkins University; set up the International Health Commission in 1913; established the China Medical Board in 1914, which established the first public health university in China, the Peking Union Medical College, in 1921; and has continued to contribute to global health since its founding in 1913 (Brown 1979; Berman 1983). Other foundations, including the Gates, Ford, Carnegie, and Robert Wood Johnson Foundations, have made similar significant contributions to public health.

Private support of public health has been implemented through three strategies: establishment of charitable foundations by industry; development of international, national, and local non-governmental organizations (NGOs); and direct contributions by industry. Each makes and can continue to make a significant contribution to the health of the public.

Foundations have contributed enormously to the advancement of public health, but most identify their own priorities for funding. Usually they provide support for important public health needs, but foundations and public health leaders do not always agree on what the most important priorities are. Massive infusions of money into public health by organizations such as the Gates Foundation, which makes contributions to fight HIV, malaria, and tuberculosis, can have a significant positive impact,

but they also tend to influence public health priorities. Some argue that developing strong public health infrastructures in developing countries will have a much greater impact on improving health than focusing funds on specific health issues (Garrett 2007).

NGOs tend to focus on specific health problems (e.g. American Cancer Society), specific health issues such as refugee health or medical care for the underserved (e.g. Doctors without Borders), and specific populations (e.g. drug users and sex workers). Often they can be more effective in reaching vulnerable populations and addressing specific health problems and issues because they are closer to the problem than health professionals who must handle a broad range of concerns. Public health programmes can increase their cost-effectiveness by cooperating with NGOs in addressing specific issues, health problems, and populations.

Industry is often viewed as part of the problem. Public health needs to convince industry to temper its profit motive to incorporate responsible citizenship at all levels. Industry is frequently a significant contributor to public health problems (e.g. air and water pollution). On the other hand, economic development can lead to an improved economic situation that reduces poverty and benefits all of society. Industry, particularly advertising, has clearly demonstrated that they are better at creating demand and influencing lifestyles than public health professionals. Thus, it behooves public health organizations to learn from industry and to work with industry to develop and implement healthy economic growth, while safeguarding the environment and benefiting the public.

Private support greatly benefited public health in the twentieth century. The challenge for the twenty-first century is for public health and private support to agree on the most effective use of private funds for achieving the greatest public health advances.

Social activism

Action by groups within society has led to improvements in the health of the public. Social activism by workers and others in the nineteenth and early twentieth century in England and the United States resulted in improved working conditions for workers in a variety of industries and to development of the field of occupational health. More recently, social activism by social groups adversely affected by HIV/AIDS led to the policy to provide access

to treatment for all with HIV infection and the need to recognize the human rights of marginalized groups in both developed and developing countries. Demands for better health conditions led by society itself are most likely to result in positive changes.

The future of public health

Public health does not lack challenges requiring solutions. Poverty is the major cause of poor health globally, yet income disparities in most countries of the world continue to grow. Developing countries must continue to cope with infectious diseases while confronting the epidemic of NCDs, further compounded by the threat of emerging diseases such as new variants of influenza. Rapid communications and transportation greatly increase the likelihood that local problems will quickly become global problems. This underscores the urgent need for much better international cooperation. An increasing proportion of the world's population will live longer. We have been successful at adding 'years to life', but chronic diseases such as Alzheimer's have reduced the quality of some of the years of life added. We must now concentrate on adding 'life to years', helping older people to continue to be healthy and productive.

We cannot afford to continue to ignore the quality of the environment. Continuing contamination of the air and water will not only cause and/or exacerbate chronic and infectious diseases, but will also compromise global food production. The world's population is still growing and, together with increasing urbanization, will further exacerbate the problem of environmental degradation.

Despite the economic and health advances of the past century, disparities between the rich and the poor in many countries are widening. This gap needs to be narrowed, not at the expense of those who are better-off, but by improving the economic situation and health of the poor and disadvantaged. The rising cost of healthcare will make closing the gap in access to healthcare even more challenging.

Injuries and violence are robbing an increasing number of people of their ability to function and to enjoy a reasonable quality of life. Injuries can be easily prevented through a variety of preventive strategies, including better design of the workplace and tools, as well as behavioural and structural approaches.

Violence and war present a particularly great challenge, and will require new strategies not hitherto widely used in public health. Public health must contribute to strategies to resolve differences between countries by promoting cross-national and international cooperation in confronting global health problems, and contribute to strategies to implement successful conflict resolution.

It is clear that the pandemic of SARS-CoV2, which has caused many deaths globally, has severely impacted the global economy and the ways in which society functions. As of this writing it is difficult to predict what those changes will be, but we must be prepared to deal with them.

Public health must convince people and provide the environment that allows them to adopt healthy lifestyles. The major strategies to combat the current epidemic of NCDs are regular exercise, a healthy diet, and development of good health habits.

Much is known about what needs to be done to significantly reduce the incidence of NCDs such as cardiovascular diseases, stroke, and cancer, but much more effective ways are needed to effect the necessary changes in personal and community behaviour, and to promote healthy lifestyles. The growing prominence of data analytics, artificial intelligence and technology raises the promise of more effective identification of at-risk groups in the general and patient populations, and more targeted and effective interventions. However, these need to be well integrated into broader public health goals and strategies.

Tremendous strides have been made to improve the health of the public, but the challenge to do better remains. In subsequent chapters, public health experts discuss the challenges and potential solutions in greater detail.

The history and development of public health in developed countries

Simon Szreter

Introduction: prioritizing the public's health and engendering economic development

It has been conventional to locate the origins of public health in early efforts to combat epidemics and to regulate the sanitary environment accompanying urban life and to trace its history in the gradual evolution of such measures in relation to politics, administrative practices, public laws, and medical science's changing aetiology (Rosen 1993; Porter 1994). Such an historical account provides important insights and understanding but it is also delimited in one significant sense. Public health is cast in a responsive role in relation to the processes of economic development. However, the nature of the relationship between public health and global economic development can appear very differently when it is viewed over the long-term, encompassing the whole process of modern economic transformation from the singular matrix of its origins in the early modern society and economy of England, c.1600–1800.

This chapter will show that state policies to promote the social order, security, and health of the population in fact pre-date and crucially underpinned the process through which the modern world's economic transformation originated—in early modern England. Furthermore, the relationship has since remained an interdependent and dialectical one. Economic development has required healthier and more productive citizens to sustain both the supply and the demand sides of the growing economy. Furthermore, as Amartya Sen has recently had to remind the discipline of economics, the purpose of economic growth is to enhance human

capabilities and functioning, not simply to amass a global stock of capital, regardless of welfare and distributional issues (Sen 1999).

The historic origins of public health policies in ensuring food security and preventing epidemics

Public health is a term which refers to a complex body of scientific expertise, policies, laws, and behavioural norms which have evolved in relation to a changing knowledge base about the prevention of harm and the promotion of health among human communities. It is also a term which refers to the observable state of relative health in those communities. Wise statecraft in the past dictated that a secure leader or government ruling over a robust polity aimed for the populace to be at least as vigorous and economically productive as those of rival states. The most elementary public health policy pursued by leaders throughout history has therefore always been the search for food security.

Given the vagaries of climate and weather, food security has posed a fundamental problem of potential disorder for leaders of settled human groups of any significant size. Threats of dearth and famine are literally Old Testament biblical themes. The importance of the relationship between sound statecraft and ensuring the public's health through food security is encapsulated in Genesis 41 in the story of Joseph's interpretation of the Pharaoh's dream of the seven fat years to be followed by seven lean years and the institution of state granaries in Egypt to preserve the people and the ruler. Ancient Chinese doctrine of an emperor's 'Mandate of Heaven' enshrined the legitimacy of popular uprising against a ruler who could not protect his people from natural disaster, including from famines. Most ancient civilizations which were sufficiently successful to have endured across many generations and to have supported the elaborate cultural productions which we now marvel at in museums, such as that of the Egyptians or the Chinese, the Incas, or the Romans, also solved this basic public health problem of food security through state-controlled granaries.

Inadequate food is the most elementary of public health threats, but sufficient and clean water is not far behind. Most historic settlements could only prosper and expand where water supplies were adequate to their needs. However, the Romans (and quite independently in South America, e.g. the

Moche-Chimú and the Incas) famously developed impressive hydraulic technological solutions which allowed settlements and cities to grow to sizes way beyond their immediately accessible water supplies. Their irrigation channels, aqueducts, public fountains, and bathing facilities were publicly funded engineering feats supplying dense populations with secure and clean water supplies, separated from the equally necessary sanitary waste systems.

Two other crucially important measures in the modern public health armamentarium which also have their genesis in much earlier practices—from the late fourteenth century onwards in Ragusa (Dubrovnik) first and then across Italy—are, firstly, the policy of physical segregation of those believed to be carrying a life-threatening communicable disease. This practice is generally known as quarantine, signalling its historic association in Europe with efforts to ward off plague outbreaks (40 days free from disease was found to be the required period to clear infected ships). It is closely related to the later practice of isolation of the infected, which lay behind the creation of separate fever wards and hospitals. Secondly, the administrative practice of counting burials, as an early warning system to monitor signs of epidemic disease outbreaks within urban populations. Also first observed in Italian city states, the most developed of these were London's weekly Bills of Mortality, which publicized the data collated from its parishes sporadically in the sixteenth century and then continuously from the early seventeenth century onwards, when they also began to include information on attested causes of death. This provided the basis for the beginnings of epidemiology in the analysis pioneered by John Graunt in his *Natural and Political Observations* of 1662 (although information on age at death was lacking until the eighteenth century).[1]

Thus, most of the key principles and policies which inform the preventive practices of 'modern' public health—and which cause it to have an integral relationship with the capacity of populations to attain high densities of settlement and associated sophisticated levels of commercial and cultural development—can be found repeatedly in history long before the advent of the most recent era of global industrialization (on earlier globalizations in history, see Hopkins 2002).

The emergence of the world's first universalist social security system in England c.1530–1830: facilitator of labour mobility,

economic growth, and the public's health

Between approximately 1600 and 1850 English society experienced a transformative rise in the material productivity of its people and economy that was without historical precedent in its speed and global reach; and it is from the proliferation of this process that all of today's developed economies and countries have emerged. Economic historians will no doubt continue to debate till the end of time the relative importance of all the different factors, both within British society and through its relationships within an expanding European, trans-Atlantic, and also global set of trading networks, which have contributed to explaining how this extraordinary process unfolded during these two centuries.[2]

However, one crucially important part of the story of this initiating episode of modern, industrial economic development relates intimately and directly to the history of a peculiarly English variant of the long-standing preoccupation of sovereign rulers with preserving and promoting the health of their subject populations. The strategy for doing this took an important, entirely innovative turn in England during the course of the sixteenth and seventeenth centuries, with extraordinary, novel implications for the productivity of the economy.

During the fateful decade of the 1530s Henry VIII broke with the Catholic Papacy in Rome, proclaiming himself head of the Church of England. One of the prime functions of the mediaeval church all across Europe had been to dispense alms to the needy, fulfilling its Christian vocation to offer mercy and charity. As the new head of the Church in England the ultimate responsibility to provide alms to the indigent poor now rested with the Crown. The Tudor state therefore needed to find an alternative, practical means to fulfil its Christian obligations to support the poor without bankrupting the Crown's limited resources, having sold off much of the rent-generating Catholic church's estates, which previously funded this activity. A sequence of experiments during the rest of the sixteenth century by Henry and his successors finally culminated in a system for placing this practical responsibility primarily on the approximately 10,000 individual parishes of the new Church of England, using the funds generated by a progressive tax rate levied on the value of land occupied by individuals within the parish. This was the famous Elizabethan or 'Old' Poor Law, enacted by statutes in 1598 and 1601. Buttressed also by a reforming 1601 Charities Act, these

Acts established an absolute right to ‘relief’—a universal social security entitlement—for every Anglican subject of the Crown in all circumstances. Parish officials (usually unpaid) had the duty, overseen by local Justices of the Peace—answerable ultimately for the fair administration of the system to the Crown—to ensure that nobody starved due to lack of work, being orphaned, old age, or illness.[3]

The parish-administered Poor Laws became the all-purpose social security and antifamine system for England and Wales, preserving the public’s health throughout the ensuing two centuries. It proved so effective it enabled the entire population to avoid completely the fundamental insecurity of famine and starvation-related disease deaths throughout this period, achieving a unique level of protection from the perennial threat which still afflicted the rural populations of the continent. The key difference in England and Wales was that every rural parish had its Poor Law fund and officers (Solar 1995). This necessitated an associated scale of public expenditure on the rural poor which French observers in the eighteenth century found literally incredible (Smith 2011). Whereas on the continent of Europe episodes of dearth resulted in raised death rates as hungry, workless, diseased rural refugees tried to make for urban centres with their grain stores, in England and Wales cash relief to purchase food was doled out to all in need in their own parishes. Unlike in the rest of Europe, after the 1620s there is no further evidence that high food prices caused peaks in death rates across England (Galloway 1988; Healey 2014). As Paul Slack has pointed out this approach to preserving social order by stabilizing the populace in times of potential disruption was also followed through in relation to the great epidemic threat of plague, where Tudor practices of isolating infected families by shutting them up in their houses, while continuing to supply them with food, were consolidated in the 1604 Plague Act (Slack 1985).

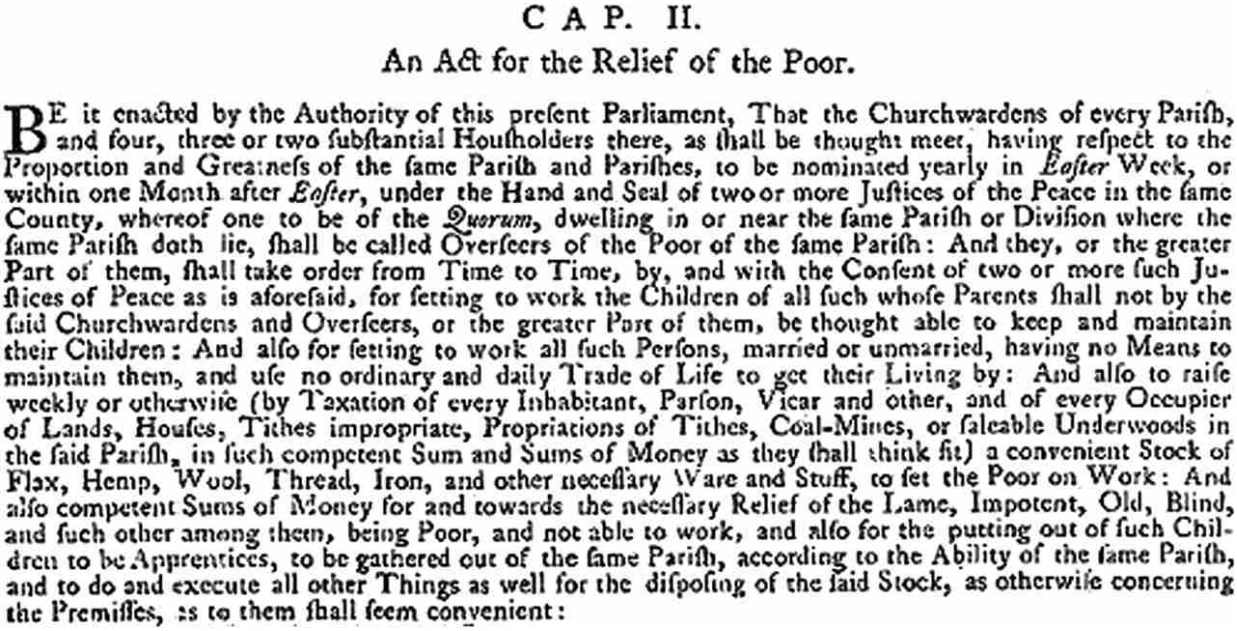
Quite unlike previous, successful antifamine strategies, as for instance that of the state granary system of the Qing dynasty in China at this very same time (Wong 2011), the English parish Poor Law did so without interrupting the normal commercial functioning of the market economy. Even when food prices were high, rather than interdicting the market price, the poor received adequate financial support to maintain them; and producers continued to make their profits.[4] The continuity of markets gave greater confidence to landlords and farmers making major investments to promote higher productivity. This raised the overall productivity of British agriculture,

enabling it successfully to feed a population of increasingly landless, urban workers which grew to proportions of the national total never previously sustained (Wrigley 1987, ch.7).

The absolute commitment, given in black-letter statute law, to maintain at parish expense all subjects of the Crown, including not only the unemployed but also the ill, orphans, and the old, was a most extraordinary mandate laid on the collective funds of each community to maintain the health of all, including a duty of care for the vulnerable—both young and old. This was an incipient free healthcare system, a comprehensive, if embryonic, public health policy. It did indeed lead to the largest proportion of the regular expenses of many parishes being consumed in supporting the incomes of the elderly in pensions, and in the building of almshouses to accommodate them and payments for doctors' fees in attending them (Williams 2011: 161–2). The most comprehensive recent study of healthcare under the Poor Law in seven provincial counties has found 15% of Poor Law funds spent on medical care throughout the period 1750–1834 (King 2018). London's largest parishes, charged under the Poor Law with caring for the vulnerable, were operating large infirmaries giving free treatment to patients throughout the eighteenth century (Siena 2004; Reinarz and Schwarz 2013). The link between illness and liability to support the poor was sufficiently obvious that leading figures across England were founding voluntary subscription hospitals at a rate of one every two years during the period 1720–75 (Slack 1990: 19, 50–1). The provincial city of Chester, for instance, was where the physician, Dr John Haygarth, trained under the great William Cullen at Edinburgh, innovated in 1783 the practice of segregated fever wards, by having a top-floor extension constructed for the Chester Infirmary; he was also an active promoter of smallpox inoculation in the region and conducted a pioneering census of the city to estimate more accurately the prevalence of different diseases. Enlightenment principles of systematic observation were leading physicians towards preventive conceptions for collective promotion of the public's health (Risse 1992).

It has been estimated that Poor Law transfer payments amounted to approximately 1% of gross national product (GNP) by 1696 and this had further risen to 2% by the 1780s (Slack 1990, Table 1). The Poor Law's primary virtue, in terms of promoting economic development, was that by underwriting security for the older generation, it released a historically novel degree of voluntary labour mobility among the younger generation. During

the initial, gradual stages of commercial expansion in the world's first industrializing economy the most important factor of production was flexible labour power, free to migrate to wherever nodes of growing labour demand were located. Between 1600 and 1800, the single statistic which consistently marked-out English society as exceptional from the rest of Europe and the world was the rapidity with which its rising generations were consistently moving, decade by decade, to urban places of manufacturing and commerce, leaving behind their ageing, landless parents secure in the knowledge that their parishes would support them (Wrigley 2004: Fig. 3.8). Parish pensions provided the elderly with an alternative security to the small subsistence patrimonies handed down from one impoverished generation to the next, as in much of the rest of Europe, including France, where the immiseration of *morcellement* is widely considered one of the underlying causes of the 1789 Revolution. Throughout history honouring and looking after elders had gone with a general need to maintain close geographic proximity; the parish Poor Law of England released the younger generation from this constraint to pursue their best options for income-earning. Furthermore, the absolute entitlement to community support muted the political consequences of the grievances of the rural poor at the productivity-raising enclosure of commons lands and the buying-up of smaller farms by larger, more commercial enterprises.



CAP. II.

An Act for the Relief of the Poor.

BE it enacted by the Authority of this preſent Parliament, That the Churchwardens of every Pariſh, and four, three or two ſubſtantial Houſholders there, as ſhall be thought meet, having reſpect to the Proportion and Greatneſs of the ſame Pariſh and Pariſhes, to be nominated yearly in *Eaſter* Week, or within one Month after *Eaſter*, under the Hand and Seal of two or more Juſtices of the Peace in the ſame County, whereof one to be of the *Quorum*, dwelling in or near the ſame Pariſh or Diviſion where the ſame Pariſh doth lie, ſhall be called Overſeers of the Poor of the ſame Pariſh: And they, or the greater Part of them, ſhall take order from Time to Time, by, and with the Conſent of two or more ſuch Juſtices of Peace as is aforeſaid, for ſetting to work the Children of all ſuch whoſe Parents ſhall not by the ſaid Churchwardens and Overſeers, or the greater Part of them, be thought able to keep and maintain their Children: And alſo for ſetting to work all ſuch Perſons, married or unmarried, having no Means to maintain them, and uſe no ordinary and daily Trade of Life to get their Living by: And alſo to raiſe weekly or otherwiſe (by Taxation of every Inhabitant, Parſon, Vicar and other, and of every Occupier of Lands, Houſes, Tithes impropriate, Propriations of Tithes, Coal-Mines, or ſaleable Underwoods in the ſaid Pariſh, in ſuch competent Sum and Sums of Money as they ſhall think fit) a convenient Stock of Flax, Hemp, Wool, Thread, Iron, and other neceſſary Ware and Stuff, to ſet the Poor on Work: And alſo competent Sums of Money for and towards the neceſſary Relief of the Lame, Impotent, Old, Blind, and ſuch other among them, being Poor, and not able to work, and alſo for the putting out of ſuch Children to be Apprentices, to be gathered out of the ſame Pariſh, according to the Ability of the ſame Pariſh, and to do and execute all other Things as well for the diſpoſing of the ſaid Stock, as otherwiſe concerning the Premiſſes, as to them ſhall ſeem convenient:

The birth of the modern Public Health movement: minimizing the costs of disease prevention

Although the Elizabethan Poor Law was the midwife to England's labour mobility and, thereby, its economic dynamism, during the second half of the eighteenth century its costs were rising as the industrializing economy disrupted and drew workers from ever larger proportions of its rural hinterland. The British economy's globally expansionary growing pains were also involving the nation increasingly in foreign wars during this same period and so the Poor Laws were picking up the indirect domestic social costs of migration, overseas trade, and war, rising 8-fold in cost c.1750–1815. It was the search by the governing class for containment of the rising costs of managing these disruptions, within a continuing commitment to universal social security, which was to dictate the shape of the world's first public health administration during the formative period c.1834–1914.

This directly resulted in the first ever national Public Health Act passed in 1848, the same year in which the continent of Europe was convulsed in republican rebellions violently put down by reactionary monarchical regimes. By contrast, Britain's 1848 reconfirmed a further stage in the

evolution of the exceptionally devolved governance system the Tudor Crown had first instituted to deal with the public policy issues of social order and social security. Although important scientific initiatives and policy ideas, relevant to the overall unfolding history of public health, can be identified as occurring in several other countries, too, such as in Austro-Hungary, France, Germany, and Sweden, it was primarily in Britain, the most economically dynamic, rapidly urbanizing, and wealthy state, that a public health administration—gradually and contestedly—first came into existence as a nationwide institution over the half-century following the 1848 Act.

Influential advocates for Poor Law reform included Adam Smith and Thomas Malthus, though their detailed arguments have been demonstrated by modern historians to have been unevidenced and incorrect.[5] Strongest support for reform in Parliament came from those seeing themselves as paying disproportionately for the Poor Law, who were principally the tax-rated landowners and farmers of the nation, not the urban industrialists (Mandler 1987). Eventually in 1834 a radically reformed New Poor Law was enacted. Jeremy Bentham's amanuensis, Edwin Chadwick, deployed his master's individualist and behaviourist pain-pleasure principle of 'scientific' government to redesign deterrence into the nation's social security system.

The new ideology of free markets and individual pursuit of self-interest deemed the collectively funded parish Poor Law an inefficient creator of dependency and pauperism and so insisted on cut-backs and deterrence. The state was attempting to withdraw systematically from intervention in society and economy, following the logic of political economy and rationalist utilitarianism replacing mercantilism and Christian mercy as guides to public policy. Although the state would continue to honour the right to relief of all subjects of the Crown, this would now only be available to those entering a workhouse to earn their keep by hard labour, with the sexes kept segregated to ensure the idle poor had no inducement to reproduce further at the expense of the community. Henceforth outdoor relief (cash doles handed to the unemployed in their homes) were supposed to cease, except for the old and the sick who genuinely could not work.

Globally expanding free trade, promoted by an increasingly dominant Royal Navy able to enforce British trading wishes even as far away as China, also brought with it more intensive intercontinental exchange of diseases, signified for Europe in the sequence of cholera pandemics, 1829–49, 1852–9, 1863–79, 1881–96, 1899–1923, each originating in India, the

prize colony in Britain's expanding commercial empire. The successive epidemics, reached Britain itself in 1831–2, 1847–8, 1853–4, and 1866–7, provoking fear and panic, even among the property-owning section of society, who increasingly sought refuge in the suburbs for their families, away from the filth and poverty of the urban centres where their wealth was manufactured.

The public health tool of information collection and dissemination, used for centuries to warn of such epidemics, was developed further, initially in post-Napoleonic France to promote public awareness of the scale of truly shocking quantities of non-epidemic, premature mortality afflicting the poorest districts of Paris, increasingly revealed from 1829 onwards in the pages of the new journal, *Annales d'Hygiène Publique et de Médecine Légale* (Coleman 1982; La Berge 1992). The pioneering French studies then inspired new official analyses beginning a decade later in Britain. William Farr had studied in 1829–30 in the Paris of the pioneering investigative hygienists such as Louis-René Villermé and Alexandre Parent-Duchâtelet and the great exponent of the numerical method, Pierre Louis, and this influenced his own statistical approach to medicine. On appointment to the new post of Medical Superintendent of Statistics at the General Register Office in 1839, Farr began to analyse the whole nation's newly instituted civil death registers to conduct a classic public health information campaign bombarding the British public and its newly freed-up provincial and national press with evidence of the egregious scale of preventable deaths occurring in the industrial cities. He innovated graphic survival tables which aimed to shock, in demonstrating that half of all infants failed to reach their fifth birthday in Liverpool and Manchester; and he went on to devise league tables of death rates to goad city's elected representatives to take action (Eyler 1979; Szreter 2005, ch.8).

From quite distinct premises Edwin Chadwick was himself coming to parallel conclusions about the costs of disease. He was vexed to find that his deterrent workhouses were not, after all containing Poor Law costs. His investigations in East London convinced him that this was because disease caused incapacity to work and hence dependence of the sick on the Poor Law (Hamlin 1997). As Hamlin points out, there were other medical leaders at this time, notably W.P. Alison in Edinburgh, who championed the more radical argument that poverty—inadequate pay and insecure employment–caused the disease revealed by Farr's statistics. The great German medical

scientist, Rudolf Virchow, having concluded from his pioneering studies of typhus among starving Polish peasants in Silesia in 1847–8 that it was due to the exploitative conditions imposed by the German aristocratic landowners, also backed socially radical policies to address workers' wages and living conditions in his new weekly journal, *Die Medicinische Reform*. However, the flawed Smithian wages fund theory prevailed at this time in Britain and increasingly across Europe, with its claim that any rise in one set of workers' wages could only be at the expense of others. It was endorsed also by the French hygienists, who accepted the Revolution's principles regarding the sanctity of private property (against monarchical despotism) and the necessity of a market economy, championed in France by J.-B. Say (Ramsey 1994, p. 57). The wages fund theory was not to be abandoned by the Victorian high priest of economic orthodoxy, J.S. Mill, until 1869. As Hamlin has shown, Chadwick's Public Health Act did not question economic orthodoxy and was devised as a pragmatic, sanitary engineering solution to specific problems he had diagnosed with the practical operation of his masterly New Poor Law.

In medical terms Chadwick's 'Sanitary Idea' was premised on the obsolescent miasmatist theory—that bad smells given off by decaying organic matter—caused disease. The notion that cleanliness was close to godliness was, however, a conventional homily of the period, appealing to MPs' common sense and to evangelical religionists (Smith 2007). The proposal to cleanse the city with an inflow of constant pressure, clean water, and an outflow of the used water through a self-scouring arterial sewers system (with the product sold to farmers as night-soil to help defray the cost) passed parliamentary scrutiny and became law. It would engineer the sanitized city, remove disease, and thereby minimize poverty and claims on the Poor Law, without in any way impugning the laws of the free market in labour.

Chadwick's sanitary city was still going to be extremely expensive to build. Westminster envisaged that most of the money would come from local taxation—rates levied on urban property values. Proud 'traditions' of liberty, sanctity of private property, and local self-government were all now mobilized against the will of Edwin Chadwick. As James Hanley's important recent study has shown, when it came to implementing the spirit of the 1848 Public Health Act or its watered-down successor, the 1858 Local Government Act, the legal battles that ensued between private landowners

and urban and other corporations, were many and protracted (Hanley 2016). The net effect was to delay by as much as a whole generation—until the 1870s—the implementation in many of Britain's fast-growing towns and cities the kind of ambitious public health scheme envisaged in Chadwick's blueprint. While urban water supplies improved somewhat after 1848, especially in textile towns where millowners wanted increased supply because of their industrial needs, it was often the sewering dimension which was neglected. Partial sewering in the better-off districts was initially left to discharge into inland rivers until this polluting practice was legally addressed through mandating treatment and filtration plants from the 1880s (Hassan 1985; Luckin 1986; Szreter and Mooney 1998).

The nineteenth-century public health movement in other developed countries

However, for all the gradualness and delay, most historians who have studied the distinctive evolution of public health history in other, comparable major countries also undergoing rapidly urbanizing economic growth, tend to portray the British as relatively hyperactive and, overall, endowed with a more effective set of institutions. In his meticulous and wide-ranging comparative examinations of England and nineteenth-century Germany, E.P. Hennock finds a relative disinterest in Germany in its appalling urban death rates and notes that the more radical German medical reformers, like Virchow, had been politically incapacitated and excluded from power by prematurely tying their flag to the failed 1848 republican revolutionary movement (Hennock 1984; 2000). By contrast Chadwick's 'Sanitary Idea' was politically brilliant, as Hamlin has put it (Hamlin 2015: 27), because it was ideologically safe. When, later in the 1880s, Bismarck initiated innovative compulsory accident and health insurance, the spirt of 1848 was long past and his primary motive was to promote productivity of the German industrial economy (Hennock 2007: 94–6).

Hygiène publique in France had been the standout scientific and intellectual leader in the wake of the French Revolutionaries' inclusion of health within their Declaration of the Rights of Man. However, the Revolution's commitment also to the sanctity of private property and an acceptance of J.-B. Say's liberal political economy became the over-riding,

safe consensus of post-Napoleonic French policy, surviving all subsequent regime changes through to 1945 (Ramsey 1994: 50, 57, 70, 82–3). There was suspicion and rivalry almost everywhere between medical professionals selling their therapeutic services in the market-place and preventive public medicine, which would seemingly undercut their market. In France this exerted an exceptionally strong influence impeding the emergence of a public health medical administration. Despite the scientific achievements of bacteriology and the Institut Pasteur in France, the power of the incumbent private practitioners ensured that even when finally a national Public Health act arrived in 1902 it did not produce a salaried public health profession—by contrast with the UK's hundreds of trained MOHs all across the country by this time. Ramsey concludes that the French medical profession has been the most privately dominated of any modern society, apart from USA's (Ramsey 1994: 99).

Indeed, in addition to USA, none of the Anglophone, developed countries beyond Europe—Canada, Australia New Zealand—followed the British lead during the nineteenth century, either in terms of a universal social security system or in creating a national cadre of medically trained public health officials with enforceable powers (Bryder 1994; Fee 1994). The thrust of the foregoing analysis is that in fact the latter absence followed from the former. Like USA, these were all frontier societies of opportunity and immigrant settlers, who bridled at paternalist authorities and associated taxes necessary for collective provision, preferring to take their chances and retain the profits of their own individualist enterprise. This meant that in the various states of Australia, although public health acts were passed, the same factors which had militated against their effectiveness in mid-Victorian Britain were even more of an impediment: local authority jurisdiction countermanding central executive initiatives in the name of upholding private property rights; disinclination to self-tax; and consequently inadequately remunerated health officials and lack of legal enforcement agencies. For instance, though Victoria passed a Public Health Act in 1854, 'marvellous Melbourne' was still a deadly city lacking a sewers system until 1897; New South Wales was unable to pass its own first Public Health Act until the year after it finally and reluctantly introduced its first Income and Land Tax Acts in 1895 (Lewis 2003: 70–90).

In the USA, despite its large number of urban centres, public health medicine was not integrated into urban government as in Britain. Although

the foundation of the APHA (American Public Health Association) dates from 1872, it was initially short of medically trained members and was relatively easy to tar with the brush of being unscientific, paternalist do-gooders when the majority of American medical practitioners subscribed to conventional individualist, free market values. New York city, having commenced the nineteenth century with a colonial inheritance of a municipally organized food supply, deregulated its public food markets in 1843 in response to commercial private interests and promptly unleashed rising inequalities in food access and quality to compound the inequalities of unregulated housing conditions, from which landlords benefitted while immigrants suffered sanitation and crowding diseases (Baics 2016). Although major cities like Chicago and New York did subsequently invest—out of sheer necessity—in municipal water and sanitation projects, nationally there was no co-ordination; not even an investigative Public Health Service until 1912. There was also no universal death registration system until 1926, the essential foundation for intelligent public health work.

Sweden was the principal other European state which did, unlike France and Germany, institute effective public health policies already in the nineteenth century. Sweden was also an early modern unified state with a Protestant established church of loyal local priests, as in England. The Swedish Crown had first become concerned to take measures to boost its population after absorbing in 1748 the disappointing results of its then-new parish population registers, the *Tabellverket*, showing a population of just two million. The following decades saw royal decrees that parishes create poorhouses and over 20 locally financed and state-subsidized hospitals were built so that illness no longer robbed the Crown of productive subjects (Johanisson 1994: 166–8). This pro-populationist public health policy was informed by mercantilism, the dominant economic orthodoxy in this era. This held that successful sovereigns accumulated the limited stock of the world's gold and silver (necessary to employ armies) through the capacity of a large and productive population to sell abroad more products than were bought-in. The mercantilist Swedish public health efforts culminated in the 1815 smallpox legislation and in the same year a unique nationally funded system to care for patients with venereal diseases—many of whom were young men of prime productive and military age, of course (Sköld 1996; Lundberg 1999).

An ambitious state public health policy could be justified on mercantilist grounds and the most comprehensive blueprint for this was the *Medicinische Polizey*, famously laid out in minute detail across nine volumes, 1779–1827, by the eminent German physician, Johann Peter Frank (Rosen 1993: 137–43). When he had begun his publications in the 1770s he had been addressing Europe's enlightened despots, such as Joseph II of Austro-Hungary. This was at a time when for instance, Austro-Hungary maintained a 1,000-mile militarized cordon sanitaire, the *Militärgrenze*, against plague incursion from the Ottoman empire (Flinn 1981, ch.4). However, neither the enlightened despots of Prussia or Russia, nor even Joseph II of Austro-Hungary actually implemented Frank's autocratic and expensive masterplan. It is generally considered that the Swedish state's policies represent the furthest practical elaboration of such mercantilist-inspired state public health measures (Porter 1994: Introduction; Sundin and Willner 2007). As with England, Sweden's historical social-inclusionary commitment to promote the population's health also fed through into early adoption of collectively funded preventive sanitary investment. Sweden's 1874 Public Health Act was strongly influenced by British experience but was passed sufficiently early in Sweden's trajectory of industrialization that it successfully prevented Sweden's urbanizing population from suffering the same epidemiological consequences as those of Britain, France, Germany, and the USA (Nelson and Rogers 1994).

Thus, among the leading industrializing countries during the nineteenth century it was mainly in Britain that important scientific advances led also to practical public health interventions, though these only really began to be extensively funded from the 1870s, when a provincial movement to promote municipal sanitation finally took-off, led by Joseph Chamberlain's mayorship in Birmingham, 1873–6 (Hennock 1973; Szreter 2005, chs.7, 9). The French had pioneered comparative epidemiology in the 1820s but it was in Britain that comparative death rates subsequently became a motivator for a nationwide movement towards the adoption of sanitary measures. Scientific leadership in the application of germ theory to identify the pathogens of communicable diseases clearly occurred first in France (The Institut Pasteur) and in Germany (Koch and the Prussian Institute for Infectious Diseases), yet it was in Britain that an extensive public system for the notification of infectious diseases was developed before the end of the century. Why was this?

Here, once again, the influence of the unusual, universal social security system of England and Wales, even though it was now in its reformed, deterrent variant of the post-1834 New Poor Law, still continued to provide a crucial influence and explanatory context. We have already seen that it was the encompassing Poor Law statutory assumptions of universalist responsibility for the poor which repeatedly led the responsible authorities into innovative forms of healthcare provision, with the building of parish almshouses followed in the eighteenth century by workhouse infirmaries and subscription hospitals; and that the need to constrain costs had led Chadwick to argue the case for sanitary investment to prevent diseases. Exactly the same logic of Poor Law cost containment, while still adhering to principles of universal provision, drove the precocious investment in disease notification in the last decades of the nineteenth century.

The moralizing aim of the New Poor Law was to end outdoor relief and drive all able-bodied workers into the labour market; however, the law recognized that the sick should instead be paid for in their own homes, not in the workhouse, as their incapacity to work was not due to idleness and in any case workhouse infirmaries did not want the risks of infectious patients. Chadwick had tried to reduce the costs of illness by sanitation in 1848. But incapacitating diseases were due to more than unclean water. Two decades later Sir John Simon, the nation's chief medical officer, was able to demonstrate statistically that infected individuals left in the community to spread their afflictions were driving up Poor Law costs and that it would be far more efficient to make a range of such diseases compulsorily 'notifiable' and to then remove the sufferers to isolation facilities (Mooney 2015: 11–12, chs. 1, 3). Mooney points out it was this administrative efficiency reasoning (and the moral and economic ideologies standing behind it), as much as microbial science, which resulted in compulsory notification for various lethal diseases with identifiable causes, such as scarlet fever, diphtheria, enteric fever (typhoid) and smallpox, beginning in London in 1889—following experiments in certain other cities—and then throughout the country with the Infectious Disease (Notification) Act, 1899. In England and Wales unavoidable fiscal responsibilities, dating back to 1601, were laid on local authorities for their sick and poor; and it was crucially this economic and politically generated framework of accountability which enabled bacteriological science to be turned into a practical, funded regime. Doctors, though they were not even state officials, were legally compelled to notify

infectious disease cases; and cities had to invest in freely provided isolation hospital facilities to make the system work as efficiently as possible while meeting its universalist commitment.

Public health in the twentieth century

Sustained global economic growth in the twentieth and twenty-first centuries has, of course, contributed a sequence of important scientific developments, with a range of potential implications for the enhancement of the public's health, such as antitoxins (diphtheria was the first in the 1890s), chemotherapies (salvarsan and neo-salvarsan to treat syphilis was the first in the 1910s), antibiotics (penicillin from the 1940s) and vaccinations (enabling smallpox to be globally eradicated in the 1970s). At the same time economic growth has contributed major new epidemiological challenges, notably the tobacco and obesity epidemics due to insufficiently regulated marketing of profitable, addictive products, HIV-AIDs, and most recently the COVID-19 pandemic, global warming, and various pollutions of land, water and air, due both to industrial practices and to affluence; and also a range of mental health-related conditions such as anorexia and depression. None of these—neither the challenging new afflictions, nor the scientific breakthroughs to counter them—can be simply attributed to the unmediated effects of economic growth on the public's health. Ideology, culture, and politics, interacting with contingent major events such as the World Wars, the Great Depression, and the Cold War, have in all cases been involved as crucial socially and politically determining influences over the exact way in which the public's health and economic growth have co-evolved differently in each distinct national polity.

Most southern and eastern European states, such as Spain, Italy, Greece, Yugoslavia, or Poland, for instance—and also those populations in the Far East, such as Japan, Singapore, and Korea, which became developed countries in terms of per capita income levels in the course of the twentieth century, did so after many of the scientific breakthroughs had been made to deal with communicable diseases and the sanitary problems of dense, urban living. In some cases, such as pre-war Japan or Franco's Spain, these advances were driven by authoritarian regimes, others were more liberal and democratic, such as postwar Japan and Italy. Provided governments promoted universal access to the necessary primary care and public health

services, their populations could achieve better health outcomes while their economies were still growing from a relatively low per capita income level, as the famous Preston curves first demonstrated (Preston 1975). The interwar period also saw the emergence of ambitious public international bodies, notably the League of Nations Health Organization and US philanthropics, such as the Rockefeller Foundation, seeking to promote public health initiatives internationally (Weindling 1995). This pattern has since expanded further in the postwar era to include the World Health Organization (WHO), World Bank, the Gates Foundations, and many other western governmental departments such UK's DfID (Packard 2016; Cueto et al. 2019). However, since Preston's publication of 1975 new global problems of growing inequality and antibiotic resistance and, most especially, pollutants and climate change are proving to be enormous health challenges for all developed and developing societies, alike. Indeed, many species are now threatened, not only poor humans. It is proving extremely challenging for national governments and powerful corporations to set aside their short-term interests to engage in a new level of global civic and political commitment to effective action, with the UN Climate Summit of 2019 the latest in a series of only partially successful attempts to bring this about. The Montreal protocols of 1987 (to address the human threat to stratospheric ozone) still remains the only such UN treaty ratified by all the world's states.

Although democracies have been strongly associated with the rise of welfare states among the economically most advanced societies since the Second World War, it is recognized that these welfare states have taken on many diverse forms influenced by their historical inheritances (Esping-Andersen 1990; Castles 2010). Germany had pioneered state social insurance in the 1880s, whereas in USA there was no nationwide Social Security Act until half a century later in the depths of the Great Depression in 1933. The Second World War, as elsewhere, further empowered public health in Roosevelt's New Deal, as the poor health of many GI recruits was revealed. However, the subsequent Cold War fears of Soviet rivalry enabled the commercial, insurance and medical vested interests once again to reassert a dominant role for private medicine in postwar USA at a time when most European developed countries were endorsing universal compulsory insurance models of healthcare for their new, fully, democratic electorates (Fee 1994: 241, 246, 249, 254). Unlike in McCarthyite USA, these were predominantly seen in western Europe, in the long tradition established by

Bismarck's pioneering 'state socialism', not as 'red', but as the best antidote to communism: social democratic methods to ameliorate working-class insecurity and grievances in a free market economy.

The UK went further than most. The principles of 1601 re-emerged, once those of 1834 were abandoned. Beveridge's welfare state was once again unconditionally universalist, supporting in principle all the vulnerable—old, young and unemployed—and was to be funded by national progressive taxation. In fact, as early as 1917 the UK government had endorsed a free national public health service, but only for venereal diseases (STIs), thereby adopting Sweden's precocious policy of a century earlier, in the interests of protecting its conscripts (Eyler 1987). From 1948 onwards the NHS meant that in principle the entire population was entitled to receive the best preventive and therapeutic medical care the nation could afford for all diseases, not just for syphilis and gonorrhoea. For instance, BCG vaccination against tuberculosis, which had been adopted in Sweden since the 1920s, now became a public health policy protecting the whole British nation (Bryder 1988: 139, 253–4).

With such universalist welfare and public health systems, national average life expectancy among most developed nations now rose above 60 for the first time in history in the immediate postwar decades as most of the sanitary and infectious diseases were tamed. Expectation of life at birth has since risen even above 80 in many advanced nations, though notably not in USA where a system of universal healthcare insurance was only introduced in 2010 and remains politically contested. The stalling of population health improvements in USA both before and since President Obama's 2010 Patient Protection and Affordable Care Act, a stalling also seen to a lesser extent in UK under the Conservative government's decision to impose an austerity policy of cuts on public services rather than additional taxes on the financial sector (despite the uncontested culpability of the latter for the financial crash of 2007–8), has drawn attention to the importance for public health of trends in socio-economic inequality. These are the two developed societies in which economic inequality and its justifying ideology of economic liberalism have had most impact on public policy during the period since c.1980, with regimes in power extolling the virtues of low-taxation and negative liberty (in Isiah Berlin's sense of individual- and therefore corporate—freedom from government regulation and intervention).

As the foregoing has shown, public health does not progress simply because of scientific medical advances or directly because of increases in average per capita income. Economic growth does not necessarily translate into public health. Ideologies which favour private, individualist wealth accumulation over more universalist, more egalitarian distribution militate against providing the funding necessary for effective public health policies. These require collectively funded measures both to prevent those with less private resources from exposure to harm in their environment, and to make available relatively equally the health-enhancing advances of the bio-medical sciences. They attempt to redress what are now termed the social determinants of health (Marmot 2008). Alternative, individualist approaches focus on behaviours and 'lifestyle risks', appearing to presume that the major causes of ill-health in developed societies today are amenable to a significant degree to personal control, even though these notably include cancers, heart disease, obesity, mental afflictions, and dementias.

Conclusions

While it is possible to produce an account of public health history in terms of a sequence of scientific advances, it is more important to examine carefully when, where, and how such advances were adopted into public health practice. Due to the complex administrative and substantial financial resources required to translate medical science into enhancements in the public's general state of health—most particularly in the highly disruptive conditions of living provoked by continuous economic growth—major conflicts of interests, ideologies, and ethics are all involved. This has meant that public health has tended to be promoted most effectively in societies subscribing to collectivist principles of welfare provision. England and Sweden were two Protestant confessional states initially influenced by mercantilist and humanist ideologies, which were historically innovative in adopting universalist principles of policy in relation to social security and health. This endowed both countries with a profoundly pro-public health commitment which has endured through different forms across the centuries. Other developed countries, both the other monarchies of Europe and the individualist, settler societies of 'neo-Europe', have only acquired such collectivist and universalist dispositions towards their citizens' health claims

much later in their histories and in the case of USA incompletely so even until the twenty-first century.

The history of public health in developed countries across the whole era of modern economic history thus reveals several major features, of which all current practitioners need to be fully aware. Firstly, the continuing long-term productivity of all modern national economies, as each century in world history has passed, has always required an ever more well-educated and generally healthy populace, not only to justify, but also both to produce and to consume an increasingly diverse and complex range of goods and services. Secondly, both the public's health and the institutional practice of public health has always been and necessarily always will be interrelated to the prevailing, wider social security system (or lack of it) in the country in which it functions. Thirdly, that this combined social security and public health matrix has enormous generative significance for the potential and the patterns of economic growth achievable in any national context. Public health, efficiently managed, is far more than a cost-burden on the economy; it is an integral, productive constituent of the character of both citizens' and the economy's future growth potential (Keating and Hertzman 1999). Finally, the public health apparatus extant in any national polity is intimately related to its political and fiscal sensitivities. These, in turn, are subject to a process of historical conflict and negotiation over the balance to be struck between Isiah Berlin's (1969) concepts of positive and negative freedoms. To what extent, within a democratic polity respectful of the rule of law, do its citizens place their trust (and taxes) in collectively provided social, environmental, and health services, as against reliance on their own private resources to purchase commercially provided variants of such services? (Nathanson 2007)

With its universalist and progressive taxation principles, the Elizabethan Poor Law statutes are, in effect, jointly the world's first social security and Public Health Act because of their coverage of the sick, the 'lame, impotent, old, blind' as well as those 'not able to work' (ER 43, cap.2 first paragraph). This extraordinary innovation may still provide a fruitful resource of ideas and administrative practices to return to, when considering the relationship between statecraft, economic development, and public health in the future of the world's developed societies.

[1] As Cipolla carefully pointed out, although the governments of several Italian city states began collating burials in 'Books of the Deceased' from as early as the fourteenth century, they did not seek to make the information public in 'Weekly Bills' circulated to the population. Since the Italian data subsequently 'remained buried … in the cities' archives' it did not contribute to the early development of demography, which occurred when John Graunt set in train a scientific public discourse based on his systematic analysis of the London Bills (Cipolla 1978: 543; Kreager 1988).

[2] For a review of the range of such interpretations, see Ahearn (2014) and Mokyr (1990: 3–6) on Solovian, Smithian, Boserupian, and Schumpeterian causes of growth.

[3] See Slack (1990: 57) on the reasons for the failure of a similar, effective parish scheme to develop in the course of the seventeenth century in Scotland (Ireland was not part of the United Kingdom until 1801). See Ishkanian and Szreter (2012: 16–17, 42–3) on the relation between the Poor Law and the Charity statute.

[4] As Wrigley (1999) notes, this was a positive effect of the Poor Laws, favourably pointed out by Malthus himself despite his generally critical disposition towards them.

[5] Smith's critique was empirically flawed because he failed properly to acknowledge the significance for labour mobility of the flexibility which certification and other widespread practices permitted (Campbell and Skinner 1976: 53–4), while Malthusian fears that generous outdoor relief encouraged the unemployed to marry too young and have too many children were also unevidenced and have since been proven to be incorrect: Wrigley and Smith (2020).

The history and development of public health in low- and middle-income countries

Than Sein

Introduction to the history and development of public health in low- and middle-income countries

Historically, public health interventions are those actions to promote and protect people's health, and are chiefly undertaken by the governments. The notion of public, within the term public health, encompasses actions for health development by the people themselves individually and collectively. Public health interventions not only deal with the control and management of both communicable and non-communicable diseases, but also address the promotion, prevention, or reduction of risks and root causes of these diseases. Fundamental characteristics of public health actions lie primarily on the social and other determinants of health that fall outside the domain of the government's health sector—and also beyond the individual's action. The majority of people in low- and middle-income countries are still living in poverty with very low health status. According to the United Nations (UN) classification of countries by their development as measured by per-capita gross national income (GNI) in 2017: countries that have per-capita GNI below US$1,005 are designated as low-income countries (32 in total); those which have per-capita GNI between US$1,006 and US$3,955 are lower-middle-income countries (38 in total); and those between US$3,956 and US$12,235 as upper-middle-income countries (42 in total). Countries with per-capita GNI of more than US$12,235 are categorized as high-income countries (UN 2018a).

This chapter describes the history and development of public health in 112 countries, classified as low-, lower- and upper-middle-income countries, also referred to as low- and middle-income countries (LMICs). The population of

LMICs (excluding those of Brazil, China, and India) is around three billion (about half of the world's population); thus, the advancement of health development in LMICs has a major impact on the health of the world. The present chapter provides an updated review of the history and development of public health in LMICs, covering the key factors and events of the last decade.

Historical development

The majority of LMICs came under the colonial territories during the eighteenth and nineteenth centuries, and some have not yet been independent until near the end of the twentieth century. The initial foundation for public health was formally laid down through the intensification of international and local public health actions by the colonialists in their territories, including international health diplomacy among themselves from the eighteenth century onwards. The United States and the European countries applied protective legislative measures and preventive actions through several series of international sanitary conventions. Soon after the League of Nations and its health organization were founded, the consciousness on public health prevention and control at the international level became more realized. The World Health Organization (WHO), the first truly international and intergovernmental agency, was founded in 1946. Its two main functions were to direct and coordinate international health work and cooperate with the Member States and partners in international health development. After WHO, several international agencies had come up under the UN to deal with health, social and economic development, such as UN Development Program (UNDP), UN Children's Fund (UNICEF), UN Population Fund (UNFPA), UN High Commissioner for Refugees (UNHCR), UN AIDS, etc. The original mandates for establishing these agencies have improved and changed over time. By the late 1990s, several international philanthropies and international civil societies had come out as major financing and development partners.

Control and eliminating old scourges

While effective prevention and control measures for old scourges like smallpox, cholera, plague, and yellow fever, that are major cripplers and

killers over the last 500 years, are available in high-income countries for centuries, a substantial portion of the world's population living in LMICs have not been able to gain access to these measures. The control of smallpox in LMICs after the invention of smallpox vaccination in the early nineteenth century in Europe was hindered by several factors, such as: impurity and variable potency of the vaccine; insufficient quantities of heat-stable vaccine; poor vaccination technique; poor coverage by the health workers due to lack of appropriate human resources; lack of commitment by the colonial administration; and lack of confidence in vaccination among the local populace. The continued global advocacy and provision of technical, material (heat-stable freeze-dried vaccines), financial, and human resources support from WHO, UNDP, and many donor countries had led to successful containment of the disease by the mid-1960s. Combined strategies of routine vaccination of children and mopping up mass vaccination, coupled with intensive case-detection, contact tracing, isolation of cases, and vaccination of individuals in the vicinity who could have been exposed to the infection, had managed to control smallpox epidemics and cut the transmission. After the last naturally acquired human smallpox case in Somalia in October 1977, in May 1980 the world was declared free from natural transmission of the smallpox virus. An international arrangement was made to create an emergency stockpile of over 60 million doses of the first- and second-generation smallpox vaccine in safe and secure places, to be used for the effective control of any smallpox outbreak that might occur (WHO 2011a; WHO 2016a). Since smallpox has been used historically as a notorious biological warfare agent, and it is easier than ever to create and spread such a deadly pathogen, the world has been warned that a bioterrorist attack that could wipe out 30 million people is becoming increasingly likely to happen (The Telegraph 2017). The 1980 eradication of smallpox by natural transmission stands out as the most successful public health intervention achieved globally in the twentieth century.

Another devastating disease, cholera, occurred worldwide for many centuries due to its severity and quick and easy spread across borders. Although it was identified as a globally notifiable disease under the old version of the International Health Regulations (IHR), report on its occurrence was no more required under the new version of IHR except in a public health emergency. Cholera remains a significant global public health problem, since 38 countries reported a total of 132,121 cases including 2,420

deaths, resulting in an overall case fatality ratio (CFR) of 1.8% in 2016. The Democratic Republic of the Congo, Haiti, Kenya, the United Republic of Tanzania, and Yemen accounted for 80% of all cases (WHO 2017a). Local armed conflicts, mass urbanization, climate change, continuing unsanitary practices (e.g. open defecation), and growing competition for water resources may, in fact, contribute to the high disease burden. Effective emergency outbreak control with good personal hygienic practices and safe water supply and sanitation remain the best preventive and control measure. Properly administered rehydration therapy and oral vaccination at the time of outbreaks could save thousands of lives. Around 20 countries affected by cholera pledged to eliminate the disease by 2030 and reduce the deaths by 90% in 2030 (WHO 2017b).

Human plague, a bacterial infection mainly affecting small mammals and transmitted by fleas but infecting humans, is often considered a problem of the ancient disease. Between 1 January 2010 and 31 December 2015, more than 3,200 cases of human plague were reported, resulting in 584 deaths, mainly occurring in 11 countries of Africa, Asia, and America. A recent outbreak of human plague with a higher frequency of pneumatic form in Africa has illustrated the breakdown of health systems due to social and political crises. The occurrence of human plague clearly demonstrates the need for strengthening surveillance on rat falls (deaths of rats around human habitats), early diagnosis and prompt treatment of human plague cases, and improved preventive and control measures in endemic countries. All these require an effective public health system (WHO 2016b). Human plague is still a global challenge as a scourge of humanity in the twenty-first century.

Another old scourge, yellow fever (YF), has been almost eliminated in several parts of Africa and South America with an effective vaccination programme, together with vector control and widespread adoption of personal protection measures. Since there is no effective specific treatment, immunization is the only means of protection against YF. The disease remains endemic in many LMICs, with an estimated 200,000 cases worldwide each year due to declining population immunity to infection, deforestation, urbanization, population movement, and climate change. While YF spreads in historical times from the original sites in Africa to the Americas, it has never established itself in Asia, where suitable conditions for the vectors and hosts exist (WHO 2017c). The reasons for this are not well understood; hence, it is difficult to assess the probability of YF

establishing itself in Asia in the near future. It could have serious consequences, given the large and dense immune-naive rural and urban population in Asia. The ongoing circulation of wild YF virus, coupled with low vaccination coverage and the presence of vector mosquitoes around the world, means that YF remains an important threat for international spread in the twenty-first century.

Elimination of childhood vaccine-preventable diseases

After increasing availability and accessibility of improved vaccines for major infectious diseases affecting infants and young children, all LMICs have commenced national immunization programmes in mid-1980, under the sponsorship of the global Expanded Program of Immunization (EPI). This global EPI initially planned to control a few childhood vaccine-preventable diseases with the ultimate aim of eliminating or eradicating them. With the continuous technical, material, and financial inputs by the Global Alliance for Vaccines and Immunization (later known as the GAVI Alliance) since early 2000, immunization coverage has been expanded both by population and antigens. Globally over 116.5 million children (85%) received a third dose of DPT (diphtheria, pertussis, and tetanus) (DPT3) in 2016, compared to 24.2 million in 1980. Measles vaccine coverage was around 70% in Africa, whereas it was over and around 90% in Europe, Asia, and the Pacific. While bacille Calmette–Guérin (BCG) and poliomyelitis vaccination remained over 80% in all WHO regions, the coverage for third doses of hepatitis B (HepB3) and *H. Influenza* (Hib3) remained below 80% in Africa (WHO 2017d). This situation highlights the need to address limited national and community resources, competing health priorities, poor health systems management, and inadequate monitoring and supervision. Despite these challenges, many public health professionals have considered the global EPI initiative a silent revolution in public health. Figure 1.3.1 shows the immunization coverage of major childhood vaccine-preventable diseases by WHO regions in 2016.

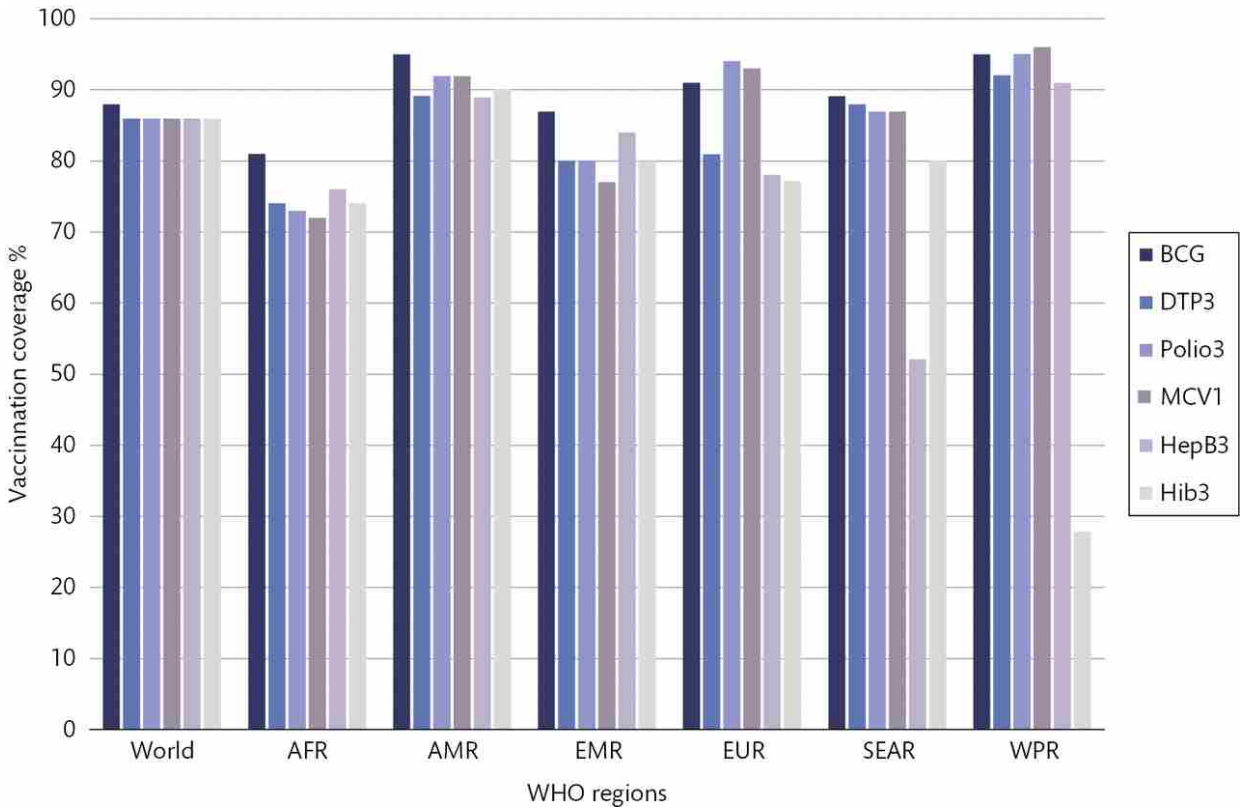

Fig. 1.3.1 Vaccination coverage of major vaccine-preventable diseases by vaccines and WHO Regions, 2016.

Abbreviations: BCG = bacille Calmette–Guérin; DTP3 = 3 doses of diphtheria-tetanus-pertussis vaccine; Polio3 = 3 doses of polio vaccine; MCV1 = 1 dose of measles-containing vaccine; HepB3 = 3 doses of hepatitis B vaccine; Hib3 = 3 doses of haemophilus influenza type B vaccine. WHO Regions: AFR = WHO African Region; AMR = WHO American Region; EMR = WHO Eastern Mediterranean Region; EUR = WHO European Region; SEAR = WHO South-East Asia Region; and WPR = WHO Western Pacific Region.

Among the vaccine-preventable diseases, the goal of eliminating poliomyelitis, an acute potentially paralysing disease of children, was launched in 1988 under the Global Eradication of Poliomyelitis programme. In the beginning, the wild poliovirus was circulating in more than 125 countries on five continents, disabling more than 1,000 children every day. With concerted efforts and additional support from the GAVI Alliance, the global coverage of polio immunization over the next two decades had reached around 80% in all WHO Regions. WHO Region of the Americas (AMR) was certified polio-free in 1994, followed by WHO Western Pacific Region (WPR) in 2000, and then European Region (EUR) in 2002. After

several rounds of vaccination against polio with designated national immunization days (NIDs), many countries were able to announce the interruption of indigenous polio transmission (WHO 2012). By 2014, the WHO South-East Asia Region (SEAR) was certified polio-free. This achievement of the majority of WHO regions marks a significant leap forward in global eradication, with 80% of the world's population now living in certified polio-free places. More than 16 million people are able to walk today who would otherwise have been paralysed. By 2018, only three countries, viz. Afghanistan and Pakistan in Asia, and Nigeria in Africa, had endemic infections due to indigenous transmission of wild polioviruses. These countries had accounted for 90% of all new cases of poliomyelitis. Failure of the global polio eradication effort, while seemingly unthinkable, would result in the return of polio infection worldwide and constitute the most expensive public health failure in history. If and when the world successfully eradicates wild poliovirus, this would represent a major milestone of public health success in the twenty-first century. Figure 1.3.2 shows the trends for the coverage of poliomyelitis immunization (three doses) for infants by WHO Regions, in 1980, and 1990 to 2016.

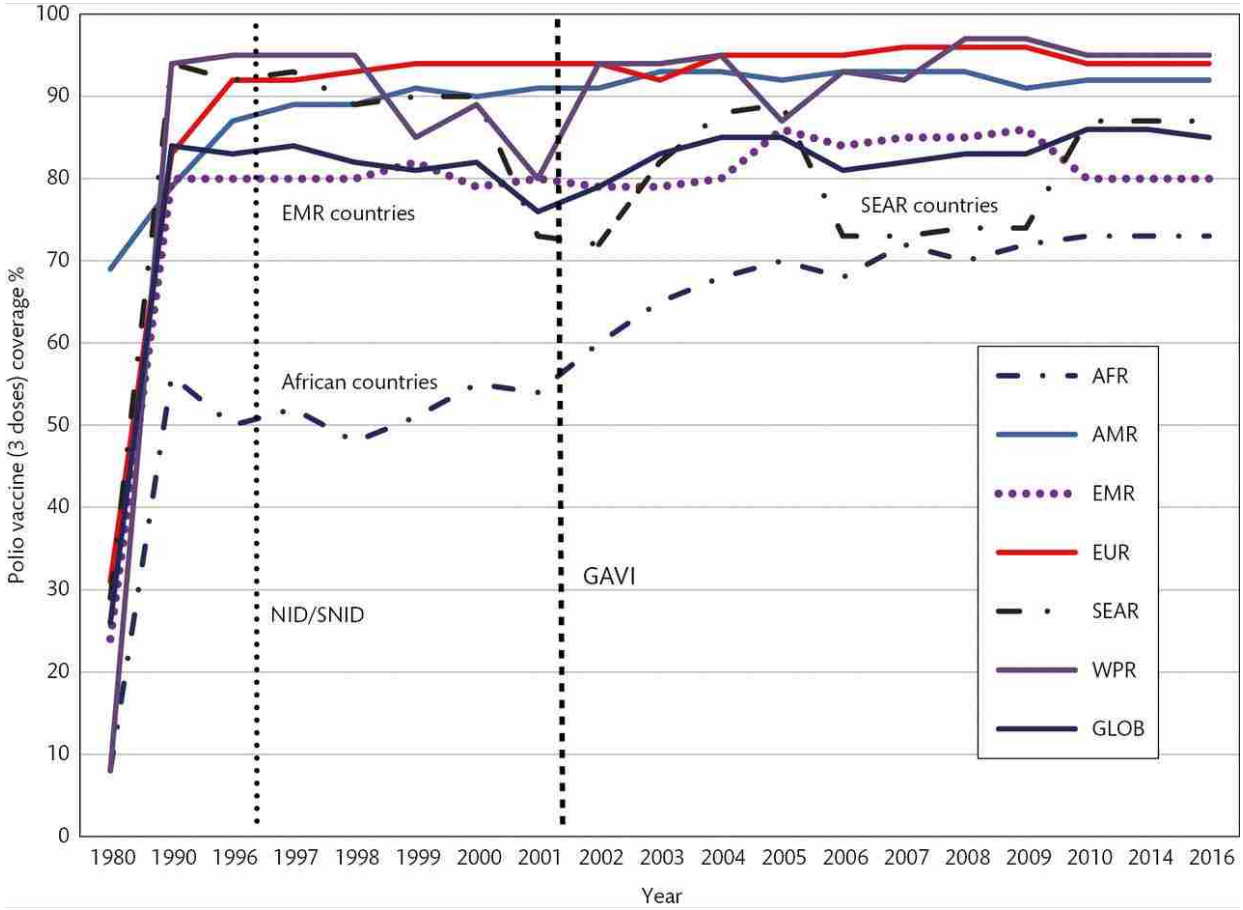

Fig. 1.3.2 Poliomyelitis immunization (three doses) coverage for <1 year of age by WHO regions, 1980 and 1990–2016.

Measles is an easily transmitted viral infection responsible for around 10% of deaths from all causes among under-five children globally, and could easily be preventable by immunization. Measles control was included as part of the routine EPI programme in LMICs since mid-1980. By 2000, 72% of the world's children received at least a single dose of measles vaccine (MCV1) (against 16% in 1980). The entire American continent had eliminated measles infection (i.e. no indigenous case for more than 12 months) by 2002. This successful experience had prompted other continents to launch similar measles elimination campaigns. From 2000 to 2016, MCV1 coverage had increased globally from 72% to 85%. The number of

measles cases reported annually worldwide decreased from over 854,000 cases in 2000 to 132,000 in 2016. For the same period, the number of measles deaths declined from 550,100 in 2000 to 89,780 in 2016 (WHO 2017e). While it may not be possible for many LMICs to eliminate measles in the near future, maintaining the high level of coverage of measles immunization of all infants (more than 85%) is nevertheless highly beneficial in reducing sickness, lifelong disability, and deaths at early ages.

High coverage of immunization with tetanus toxoid (TT) to all women of childbearing age and high coverage of DPT vaccine for infants and with boosters among school children, are the simplest and most cost-effective ways to reduce tetanus infection in women and neonates, as well as deaths due to neonatal tetanus (NNT). Efforts have been made since 1989 to eliminate the disease (i.e. reducing the level of incidence of one NNT case per 1,000 live births in all districts of the country). However, by 2016, around 25 countries of the world, all from LMICs, remained tetanus endemic.

Immunization against *hepatitis B* (HepB), another highly prevalent viral infection of the liver that could lead to cirrhosis and cancer, was introduced as part of a routine EPI programme in 183 countries since early-1990. Approximately 257 million people live with hepatitis B virus infection (defined as hepatitis B surface antigen-positive). In 2015, hepatitis B resulted in 887,000 deaths, mostly from complications (including cirrhosis and hepatocellular carcinoma). For the last 25 years, almost all LMICs have used both plasma-derived and recombinant HepB vaccines, achieving over 80–90% coverage globally in 2016 (WHO 2017f). If the continuous vaccine supply can be ensured and the high coverage maintained, HepB infection could be under control and even eliminated within the next two decades.

A potent vaccine against another viral infection caused by *Haemophilus influenzae* type b or Hib has been available since mid-1990, being introduced under routine immunization programmes in 189 countries. Global coverage with three doses of Hib vaccination was estimated at around 52%, while some regions have better coverage of over 90% (WHO 2006a).

Control of neglected tropical diseases

A group of infectious diseases that cause illness and death of thousands of people living in the tropical zones worldwide have been neglected for

various reasons for complete prevention and control. Leprosy, the most neglected tropical disease (NTD), has been put under control by accelerated efforts in the last 25 years with the introduction of multidrug therapy (MDT). By 2001, 107 of 122 endemic countries were able to achieve the global target of leprosy elimination (i.e. reducing the prevalence to a level below one case per 10,000 people). Globally, the number of new leprosy cases reported from 143 countries had come down from a peak of over 775,000 cases in 2001 to 214,783 in 2016. Over 90% of the new cases during the last decade were represented from 22 priority countries in Asia, the Pacific, and Africa (WHO 2017g). If the current trend in disease reduction in endemic countries is well sustained with full support from the Global Alliance, the incidence and total burden of leprosy could be further reduced in the near future. Leprosy elimination could be another public health landmark during the twenty-first century.

Trachoma is a chronic infection of the eyes by the bacterium *Chlamydia trachomatis*, mainly affecting poor people and children living in 41 tropical countries of Asia and Africa, especially in areas where unhygienic personal practices still prevail and inadequate access to safe water supply, and is responsible for the blindness or visual impairment of about 1.9 million people. Under the national integrated trachoma control programme, many endemic countries implemented the WHO-advocated SAFE strategy (surgery, antibiotics, facial cleansing, and environmental improvement). In 2016, 190.2 million people still lived in trachoma-endemic areas and are at risk of trachoma blindness. Global-level antibiotic coverage was 44.8%, a considerable increase compared to the 29.6% achieved in 2015. As of 1 July 2017, 10 countries (Cambodia, China, Gambia, Ghana, Islamic Republic of Iran, Lao People’s Democratic Republic, Mexico, Morocco, Myanmar, and Oman) had reported achieving elimination goal, which signifies a major milestone in the campaign to eliminate trachoma (WHO 2017h).

The global effort for eradicating yaws, another disabling NTD, has been launched in many LMICs around the world in the last five decades through mass vaccination programmes and effective mass treatment. However, sporadic epidemics and scattered foci of infection persist in some parts of Latin America, the Pacific, and South and South-East Asia. Extensive surveillance and case finding, use of newer antibiotics, and follow-up of treated cases and contacts became important strategies for the eradication of yaws in the remaining endemic countries.

Visceral leishmaniosis or kala-azar, another NTD, has been put under control by using an oral medication, *Miltefosine*. Until newer medicines and appropriate vaccine(s) are available at affordable prices, and made accessible to the mass population in the endemic countries, the misery and suffering of thousands of people from visceral leishmaniosis would continue.

Onchocerciasis, also known as river blindness, is another parasitic infection still endemic in 37 countries in Africa and Latin America. A million people are visually impaired, and over 300,000 people are blind due to this disease. The Global Onchocerciasis Control Program launched in 1974 had tried to reduce severe pathological manifestations through community-based mass management with a microfilarial drug (*ivermectin*) combined with vector control. Although the disease is a preventable cause of blindness and its elimination goal is achievable, there is a great deal of work to be done by the health systems in endemic countries (Diawara et al. 2009).

Dracunculiasis is a vector-borne guinea worm infestation, but an eradicable disease, as diagnosis is easy and unambiguous, and control interventions are simple, cost-effective, and relatively easy to implement. The disease has limited geographical distribution and transmission is seasonal. Many endemic countries in Asia and Africa with strong political commitment from governments were able to achieve the global eradication target set in 2004 by reducing the annual incidence from 3.5 million in 1986 to less than 1,100 cases in 2011 (WHO 2011b). As of 31 December 2015, 196 countries, territories, and areas have been certified free of dracunculiasis transmission. By 2016, the disease was confined only to three endemic countries (Sudan, Chad, and Ethiopia), where less than 30 cases were reported (WHO 2018). The challenge for eradication efforts in these countries is the emergence of another host, i.e. domestic dogs (Molyneux and Sankara 2017). If concerted efforts continued, eradication of dracunculiasis could be achieved in the near future without any use of vaccine and medicine.

Lymphatic filariasis (LF) is also a disabling NTD caused by blood-borne infection of microscopic thread-like parasitic worms—*microfilariae*. The global programme to eliminate LF through mass drug administration (MDA) was launched in 2000. With 556 million people in 39 of 73 endemic countries treated during 2015, the cumulative total of MDA now exceeds 6.2 billion. A total of 18 countries have halted MDA nationwide and six of these (Cambodia, Cook Islands, Maldives, Niue, Sri Lanka, and Vanuatu) were

acknowledged by WHO as having eliminated LF as a public health problem. Nonetheless, 2738 implementation units across 54 countries, with approximately 946 million people, are still considered to require MDA to achieve elimination targets (WHO 2017i).

Controlling non-communicable diseases

While communicable diseases continue to be major public health problems, chronic non-communicable diseases (NCD) are emerging in LMICs as public health challenge for the 21st century. In 2015, an estimated 40 million deaths occurred due to NCD, accounting for 70% of the overall total of 56 million deaths. The majority of such deaths were caused by the four main NCD, namely: cardiovascular disease—17.7 million deaths (accounting for 45% of all NCD deaths); cancer—8.8 million deaths (22%); chronic respiratory disease—3.9 million deaths (10%); and diabetes—1.6 million deaths (4%) (WHO 2017j). Many large-scale, well-designed population-based control programmes had shown that lowering the common risk factors like tobacco and alcohol use, high sugar or salt including unhealthy diets, can reduce morbidity and deaths from NCDs. The dual approach of early screening and mitigating risk factors, and promoting population-wide preventive measures like policy and legislation is an appropriate strategy for LMICs.

Diabetes mellitus, either insulin-dependent (Type 1) or non-insulin-dependent (Type 2), has affected around 200 million people of above 20 years of age worldwide. Gaps in early diagnosis and treatment of diabetes in LMICs are the biggest challenges, and health systems are not well-prepared for narrowing these gaps. The number of patients with diabetes may increase to 370 million by 2030, if proper promotive, preventive, and control strategies are not in place. With early screening and diagnosis followed by effective management with diet, exercise, and essential medicines, diabetes, and its complications can be potentially controlled.

Cancer is a well-known NCD and a leading cause of death worldwide, with more than 70% of all cancer deaths occurring in LMIC. Liver cancer affects approximately 5.5 million people, predominantly caused by viral hepatitis B and C. Stomach cancer caused by *Helicobacter pylori* infection could be easily prevented by early prevention and control of infection with appropriate medicines. The global burden of cancer in women has recently

received much attention, but there are few comprehensive reviews of the burden and policy approaches to reduce it. Early detection with proper screening and improved breast cancer treatment has reduced mortality by 45% in women above 50 years of age. Cancer of the uterine cervix, which is prevalent among women of childbearing age, is mainly due to chronic infection with sexually transmitted *human papillomavirus* (HPV). In LMICs, cervical cancer is the leading cause of cancer death in women, and 91% of global estimated HPV-related cancer deaths are due to cervical cancer. HPV vaccines are very effective at preventing the disease, and the protection lasts for at least 5 years (WHO 2009). Pap smear screening and early treatment also significantly reduced mortality from cervical cancer.

There are examples of proven public health interventions with a particular focus on the primary prevention of risk factors. Many of these measures are extremely cost-effective, especially in the case of tobacco control and vaccination against cancer-causing diseases. LMICs must prioritize efforts to reduce known cancer risk factors and make prevention and treatment accessible to all. Early diagnosis, effective treatment, and palliative care are also required. Expanding population-based cancer registries and research in LMICs are needed to set cancer control priorities and determine the most effective interventions.

Environmental health promotion

For centuries, the promotion of environmental health, including public housing, public water supply, personal hygiene, and sanitation, has been recognized as key elements for public health development. Despite legislative measures supplemented by public health education campaigns, public subsidy support, and private donation, the progress in environmental health (specifically safe water supply and sanitation) in LMICs has not been satisfactory. According to WHO, the population using improved drinking-water sources in LMICs had increased from 70% in 1990 to 87% by 2010, while the population using improved sanitation in the same group of countries in 2010 was still less than 50% (WHO 2017j). About 2.4 billion people around the world, mostly in Asia and Africa, were still lacking access to improved sanitation facilities, mainly due to low priority given to the sector, inadequate financial resources, and lack of sustainable public water

supply and sanitation services, especially the existence of unimproved sanitation and open defecation, and poor personal hygienic practices.

The situation is exacerbated by inadequate provision of public water supply and sanitation facilities, even in public places like wet markets, parks, movie theatres, schools, hospitals, health centres, offices, and religious places. Providing access to low-cost, adequate, and simple, improved drinking-water sources and improved facilities for sanitary disposal of excrement, and promoting sound hygienic behaviours among the general population in LMICs is of critical importance in reducing the burden of communicable diseases. Given the current economic growth prospect, LMICs have the challenge of getting additional financial support from external agencies, in order to achieve the UNSDG for environmental health improvement (WHO/ UNICEF 2017).

The UN Sustainable Development Goals (SDGs) on health has a target that by 2030, there will be substantially reducing the number of deaths and illnesses from hazardous chemicals and air, water, and soil pollution and contamination. Around 4.5 million deaths occur every year as a result of household exposure to smoke from dirty cook stoves and fuels, and 3 million deaths every year as a result of exposure to ambient (outdoor) air pollution. Most air-pollution deaths are premature deaths, largely as a result of increased mortality from stroke, heart disease, chronic obstructive pulmonary disease, lung cancer, and acute respiratory infections. People living in LMICs disproportionately experience the burden of outdoor air pollution, with 87% of the 3 million premature deaths (WHO 2016c). Policies and investments supporting cleaner transport, energy-efficient housing, power generation, industry, and better municipal waste management, agricultural waste incineration, forest fires, and certain agro-forestry activities (e.g. charcoal production) would reduce key sources of urban outdoor air pollution.

Climate change and its impact

Climate change is now affecting every country on every continent. It is disrupting national economies and affecting lives, costing people, communities, and countries dearly today and even more tomorrow. People are experiencing the significant impacts of climate change, which include changing weather patterns, rising sea levels, and more extreme weather

events. The greenhouse gas emissions from human activities are driving climate change and continue to rise. Without action, the world's average surface temperature is projected to rise over the twenty-first century. It is likely to surpass 3ºC this century—with some areas of the world expected to warm even more. Implementation of the Paris Agreement adopted in 2015 provides a roadmap for climate actions that will reduce emissions and build climate resilience (UN 2018b).

New generation of health systems reforms

For effective control of both communicable and NCDs and their risks, there is a need to have viable and efficient health systems. Historically, many LMICs tried to establish their healthcare facilities and public health measures, based on the models of their colonial masters. In general, these health systems were publicly funded, except in some African countries where basic healthcare relied upon health facilities and staff supported by non-governmental organizations. Several medical schools and paramedical training institutes, public health training and research institutions and healthcare facilities were later added with technical and financial assistance from their colonial rulers.

Health systems development in the twenty-first century

Until mid-1970, many LMICs had weak health infrastructure for maternal and child health (MCH) care and communicable disease control, leading to high mortality and morbidity from maternal and childhood illnesses. Immunization coverage for children was very low, and essential MCH care had to rely on poorly trained human resources at hospitals and hospital-based clinics, located mostly in urban areas. It was later realized that the vertical approach of opening MCH centres and deploying MCH workers alone did not achieve the purpose of expanding MCH care. In 1980–1990, many LMICs started adopting comprehensive population policies and family planning services as part of MCH care to address both demographic challenges and maternal health problems. Even though simple and effective family planning techniques were available and within reach globally, only a fraction of women in LMICs could have access to these services.

Another critical challenge is making essential medicines affordable and accessible for needy patients. While many newer food supplements, medicines, and vaccines have been made available to the vast population, the control of substandard, spurious, falsely labelled, falsified, or counterfeit medical products has become a big challenge. LMICs must continually strengthen their food and drug regulatory agencies to ensure effective implementation, especially control of these counterfeit, substandard, spurious medicines. With the expansion of the private sector and health insurance, ensuring access to, and—in particular—affordability of essential medicines and vaccines become more vital.

Healthcare systems utilizing varieties of health professionals and allied health workers, hospitals and modern allopathic medicine intended to benefit the whole population barely existed a century ago in many LMICs. To date, major responsibility for healthcare provision in LMICs is through the publicly financed health facilities in conjunction with private healthcare providers. The development of infrastructure for public health, mainly for prevention and control of communicable disease, solely depended upon the support and expansion of vertical disease control campaigns such as vaccine-preventable diseases, HIV/AIDS, malaria, tuberculosis, or reproductive health, supported with international funds.

There are glaring contrasts between high-income countries and LMICs as well as among LMICs themselves in achieving a higher level of health status. The average life expectancy at birth in 2015 in low-income countries was around 62 years, and that of lower-middle-income countries was around 66 years, while the data for upper-middle and high-income countries ranged from 74 to 80 years (WHO 2017j). Many low-income countries still have an under-five mortality rate of above 120 per 1000 live births.

At the turn of the twenty-first century, while some countries still concentrated on vertical campaigns for expanding personal healthcare interventions like MCH, family planning, growth monitoring, breastfeeding, and immunization, as well as vertical disease control campaigns for malaria, HIV/AIDS, TB, etc., other LMICs tried to implement comprehensive health programmes including health legislative and health finance reforms. There was inadequate coordination and collaboration among specific health intervention initiatives, like immunization or specific disease campaigns or capital investment for hospital care on the one hand, and the development of basic health systems infrastructure on another. This dichotomy situation

resulted in the inadequate involvement of communities in their health development efforts and the slow pace of integrating vertical disease control campaigns into the basic health services. It was compounded by weak planning and management of health development, especially at the operational levels at districts and below, and the imbalance and inappropriateness of some human resources for health.

Some LMICs acknowledged that their health development programmes utilizing the conventional approach of merely expanding basic health services were inadequate. The public sector could not bear the cost of expanding basic healthcare services to the entire population in the face of existing resource constraints. Thus, many countries sought partnerships with private healthcare providers, worked with community-based civil society organizations, and deployed a large number of community-based health workers, who were volunteers and trained for short periods to serve as a third workforce of human resources for health (Sein 2006; WHO 2007). The increasing use of community-based volunteers in health development had proved successful for quickly expanding essential healthcare coverage in many countries. With the involvement of private healthcare providers and community-based health workers, many essential public health interventions were enhanced, especially in disease prevention and control, health promotion, maternal and child healthcare, information gathering and surveillance, treatment of minor ailments, and environmental health promotion.

Health policy, planning, and financing

The centrally directed health planning framework applying country health planning (CHP) or national planning process for health sector development, supported by WHO and UN agencies during 1970–1990, had moved many LMICs to a higher level of health attainment. It was highly successful when the health development programmes based on selective healthcare interventions, like immunization, malaria, leprosy, HIV/AIDS, or tuberculosis control, or selective maternal and childcare and family planning, growth monitoring, were promoted on the national scale through centrally controlled, externally funded programmes. In the late 1990s, the development partners moved their financing aid from planning multiple

vertical health development projects, to integrated sectoral planning of comprehensive health development programmes.

Around 2005, the UN introduced the principle of delivering as one (DaO), basically covering four areas—one leader, one budget, one programme, and one office, especially to integrate multiple UN-supported national programmes under one umbrella. The UN also worked with multiple development partners to establish the multi-donor trust fund (MDTF) mechanism by pooling multiple donor-supported funds into one integrated plan, and getting more partners to support a single national strategy in selected LMICs (UNDG 2010). A group of development partners, led by WHO and the World Bank that share a common interest in improving health services and health outcomes for LMICs, in 2007 launched another global initiative called the International Health Partnership plus related initiatives (IHP+). An interagency working group of IHP+ had developed a joint assessment tool for national health plans and strategies (JANs) and associated guidelines in 2009. Since 2010, the JANs tool was applied in several LMICs as part of the national health policy development and planning process (WHO 2015b). The national health planning processes now cover a comprehensive, balanced, and evidence-based assessment of the country's health and health system challenges. Many LMICs tried to strengthen their institutional capacity to harmonize and align donor programmes with their national policies, strategies, priorities, and plans.

LMICs, while struggling to improve their health systems, increasingly realized the value of financially protecting their own people in the fairest way possible. The key challenge of reform in health financing in LMICs, particularly the collection of revenue and pooling and use of financial resources, is to find a good balance between affordability and fairness to the people while providing appropriate incentives to healthcare providers. This is in keeping with the ideal for universal coverage, which means equity of access to key promotive, preventive, curative, and rehabilitative health interventions for all at an affordable cost (WHO IBRD/WB 2017).

In 2015, the world had spent US$ 7.3 trillion on health, close to 10% of the global gross domestic product (GDP). In fact, high-income countries with only 16% of the world's people account for 80% of global health spending. Conversely, 76% of the world's people living in middle-income countries accounted for less than 20% of global health spending, and the low-income countries with more than half a billion people accounted for less

than 1% of the world's health spending. In 2015, the global average health spending per capita was US$ 1,011, which conceals a very large difference between the highest and lowest spending countries, ranging from over US$ 9,000 to less than US$ 20 per capita. People spend more on health through out-of-pocket payment (OOP) in constant absolute terms for all income groups. Today, there are one billion people living in countries where out-of-pocket spending is 50% or more (WHO 2017k).

The way healthcare is financed varies considerably across countries. Middle-income and high-income countries tend to have a higher share of health spending funded from compulsory prepaid sources, such as government budgets (from various types of taxes) and/or social health insurance contributions. Many LMICs still rely heavily on external assistance to health expenditure, estimated at about 33% on average. Middle-income countries with high reliance on external resources are almost all exclusively small states. There is evidence of the fungibility of external funds, particularly in low-income countries. In addition, there is evidence of non-additionality of development assistance for health, where development assistance is spent in the health sector, but the recipient government re-allocates its own resources to fund other priorities (WHO 2017k). The proliferation of bilateral and multilateral donors, multiple global initiatives, and international non-governmental agencies (NGOs) also generates the potential to weaken health systems rather than strengthen them, allowing countries to avoid issues like long-term sustainability.

Strengthening health workforce for 2030

One key factor for success in public health and health system development is having a critical mass of competent health workforce. As human resources consume as much as 60–70% of the public health expenditure, they need to be fully developed and optimally utilized. The World Health Report 2006 had provided a global analysis and identified effective strategies to strengthen the development of appropriate human resources for health (WHO 2006b). There is an anticipated mismatch between demand, need, and supply. In addition, there is an acceleration of domestic and international migration of all types of the health workforce. Furthermore, the challenge of deploying and retaining health professionals in rural, remote, and underserved areas is truly global. The major reasons for the health workforce

shortage, while varying greatly among LMICs, include inadequate numbers of human resources due to under-investment in basic undergraduate and graduate education and training; loss of existing workforce due to emigration to other countries; mismanagement and coordination; and inefficient planning. Newer models of deployment, health workers' education, and management are in need (WHO 2016d).

Some of the impediments to the development of a relevant and adequately sized public health workforce are lack of incentives and career structure for public health professionals, public health training being seen as an extension of the biomedical model of clinical training, and the inclusion of many training courses and core curriculum which are either obsolete or irrelevant to the public health needs of the countries. Several networks, both formal and informal, among public health education institutions in Asia and Africa have been established to collaborate and support exchange programmes for faculty members and students, sharing of curriculum and training materials, and organizing joint research studies.

Health research and development

While science and technology research and development and their application have advanced rapidly in high-income countries, these disciplines have remained rudimentary in LMICs. Many LMICs must rely on the results of research and development on pharmaceuticals and vaccines from high-income countries, and in fact, many breakthroughs have been contributed by the experiences gained and the studies carried out in LMIC. In many LMICs, there are very few health research and development institutions as well as poor career prospects for researchers.

Joint collaborative studies between LMICs, especially upper-middle-income countries, and the high-income countries, are carried out for the development and use of medicines and vaccines for infectious diseases, promotion of human health and reproduction specifically on contraception and other fertility control measures, strengthening of health systems, promotion and protection of environmental health, and control of NCDs, and development of essential healthcare technologies. Considerable progress has been made in capability strengthening for promoting health systems research, which has further paved the way for developing effective national health research systems.

In recent years, the development of health research has been promoted through international exchanges of experience and expertise among the networks such as INCLEN Trust, Asia-Pacific Health Research System Network and African Health Research System Network. A major issue faced by LMICs today is that while scientific advances and technological development of the high-income countries provide them with vast opportunities for their overall economic development, many people in LMICs are still suffering from preventable NCDs, neglected tropical diseases, and under-nutrition.

Strive for social determinants of health

Many LMICs are particularly susceptible to the negative impact of socially determined health inequities due to heavy exposure to health risks, social exclusion, and other broader determinants associated with health risks, including low-income, unsafe living conditions, poor work environment, unsafe sex, and changing consumption patterns of food, water, and information. LMICs considered the need to build up their national capacities to address advocacy, intersectoral action, evidence gathering of health inequity, and social determinants across sectors.

Reducing tobacco and alcohol use

Tobacco is the most common risk factor for many NCDs. In 2015, more than 1.1 billion people smoked tobacco, with far more males than females currently engaging in this behaviour. Tobacco-related illnesses and deaths had increased globally during the past decades with seven million deaths every year, and if no proper control measures are instituted, the death toll may go up to 10 million in the next decade. In LMICs, the increasing use of betel-quid (betel leave combining betel-nut, slake-lime, and tobacco) has become a major issue, since it causes oral, laryngeal, and gastrointestinal cancer, and cardiovascular diseases. After adoption in May 2003 of the WHO Framework Convention on Tobacco Control (WHO FCTC), LMICs have either adopted or amended their tobacco control legislation, conforming to the provisions of the WHO FCTC. By 2017, 180 parties to WHO FCTC had ratified the Convention, and adopted tobacco control measures called MPOWER (M for monitoring tobacco use, P for protecting people from

tobacco smoke, O for offer help to quit, W for warning about dangers of tobacco, E for enforcing ban on tobacco advertising, promotion and sponsorship, and R for raising tax for tobacco), the six best-buy strategies promoted by WHO and adopted by all parties to WHO FCTC. Around 4.77 billion people are covered by at least one best practice policy intervention at the national level, a substantial increase from nearly two billion people (WHO 2017l). There is also an urgent need to make effective control for e-cigarettes, water pipes, and heated tobacco products, as they became newer forms of tobacco marketed to LMICs. It is critical that all countries act urgently to protect their people more effectively with evidence-based tobacco control policies at the most comprehensive level.

Worldwide consumption of alcohol has increased from 6 litres of pure alcohol consumed per person aged 15 or older, in 2008, as compared to 6.4 litres of pure alcohol per person aged 15 years or older, with considerable variation between WHO regions, in 2016. A large portion of this—28.6% or 1.76 litres per person—was homemade, illegally produced or sold outside normal government controls (WHO 2017j). Harmful use of alcohol is a major factor contributing to premature deaths and avoidable disease worldwide. A wide range of policy options and interventions for reducing public health problems caused by the harmful use of alcohol was advocated for all countries.

Preventing injuries

Injuries, caused intentionally and non-intentionally, have emerged as a major public health problem in the twenty-first century. Globally, road traffic injuries claim more than 1.2 million lives each year and greatly impact health and development. The rapidly rising number of motor vehicles (48% of the world's vehicles are registered in LMICs), and motorcycles (adding more than a million a day on the roads) has led to an equally rapid increase in traffic-related injuries and deaths. LMICs have a higher road-traffic-related death rate of over 20 per 100,000 population, and accounted for over 90% of the world's fatalities.

They are the leading cause of death among young people aged between 15 and 29 years, and cost governments approximately 3–5% of GDP. The rise in global road traffic deaths has been largely driven by the escalating death toll on roads in LMICs—particularly in emerging economies where urbanization

and motorization accompany rapid economic growth. In many LMICs, necessary infrastructural development, policy changes, and levels of enforcement have not kept pace with increasing vehicle use. Introduction and upgrading of safe public transport, improvement of road signs and pedestrian crossings, compliance with traffic legislation like wearing helmets and seatbelts, and avoiding speeding and drink-driving, are important measures for reducing road traffic injuries (WHO 2015). In addition to deaths on the roads, up to 50 million people incur non-fatal injuries each year as a result of road traffic crashes, while there are additional indirect health consequences that are associated with this growing epidemic. The UN SDG3 target aims to halve the number of global deaths and injuries from road traffic crashes by 2030, while SDG11 relates to providing access to sustainable transport systems for all, improving road safety, and expanding public transport (WHO 2016d).

Nutrition promotion

Despite the significant steps taken towards promoting nutrition and reducing associated health burdens over recent decades, the global community is grappling with multiple burdens of malnutrition. Global Nutrition Report (2017) showed that 88% of countries face a serious burden of either two or three forms of malnutrition (i.e. childhood stunting, anaemia in women of reproductive age, and/or overweight in adult women). It also indicated that progress on global nutrition targets is slow or moving backwards. Around 2 billion people lack essential micronutrients like iron and vitamin A in their daily diet, 155 million children have stunted growth, 52 million children are wasted, while 41 million children are obese. 88% of 193 UN member countries have faced a serious burden of either two or three forms of malnutrition (Development Initiatives 2017). There is an opportunity to identify—and to take—double-duty actions at once which tackle more than one form of malnutrition. These will increase the effectiveness and efficiency of the investment of time, energy, and resources to improve nutrition. Likewise, triple duty actions which tackle malnutrition and other development challenges could yield multiple benefits across the UN SDGs.

Social medicine and public health

The initial idea of social medicine or the social dimensions of public health had emerged in the early twentieth century. The concept of social medicine was developed as a new public health discipline in the late 1940s. At that time, the leaders of both clinical medicine and public health questioned the perceived polarization of curative medicine and preventive medicine. The situation was exacerbated by continued specialization and the lack of cross-disciplinary interaction (Ko Ko 2011).

The social and behavioural aspects that influenced illness and well-being are recognized again, and revisited during the dawn of the twenty-first century. Many social and personal behavioural interventions are introduced as part of health promotion and disease prevention. Many universities and medical schools converted their departments, faculties, or schools of hygiene and public health into those of preventive and social medicine from the 1960s. Instead of integrating curative and preventive medicine in the teaching of social medicine, educational institutions equated public health and hygiene with preventive and social medicine, and conventional public health teaching still has a primary focus on the prevention and control of infectious diseases and hygiene. The general population is now becoming increasingly aware of the social and economic determinants impacting health. As a result, national debates at both public and political levels on health linkages with social, environmental, economic, and political factors are needed. There are more discussions at the global level to give a wider political and social dimension to international public health.

The history of public health development has shown the need for increased cooperation between high-income and LMICs to promote the total health and well-being of all world citizens. Over the past 50 years, many international, intergovernmental, bilateral, and multilateral development agencies and organizations, as well as professional and technical alliances, have emerged out of necessity to deal with international health developmental issues both in policy and programme terms. Partnerships could be established to sustain and support health system development so that equitable health outcomes are achieved and the needs of the people are met. More recently, debates have intensified around global public health development and the global governance of health (Kickbusch and Gleicher 2012).

Whither to new public health

Now, entering the twenty-first century, many LMICs move towards another era of public health development with new thoughts from a narrow view of vertical disease control interventions to a wider perspective of multisectoral interventions beyond the health sector. Besides the usual public health measures undertaken by the governments, an increasing number of NGOs and the private sector agencies, both at the local and global level, were involving in public health development. In addition to external financing and technical support by traditional international agencies like WHO and UN, bilateral aid agencies from high-income countries and multilateral financial institutions like the IBRD, the World Bank, and Regional Development Banks, there are a myriad of multinational foundations, international funds, and financing groups like the GAVI Alliance and the Global Fund, as well as private international foundations like Bill and Melinda Gates Foundation or Bloomberg Philanthropies, etc., that have transformed international health support and governance on national and international health cooperation.

Globalization of public health

The UN had launched the Joint UN Program on HIV/AIDS (UNAIDS) in January 1996, with the UN-wide mission to lead, strengthen and support an expanded response to HIV/AIDS. Another UN initiative was the adoption of UN Millennium Development Goals (UN MDG), with targets for 2015, representing the world's commitment to deal with global poverty and health in several dimensions (UN 2011). After reviewing the progress of UN MDG, the UN Summit in 2015 adopted a development agenda titled—Transforming our world: the 2030 Agenda for Sustainable Development, which contained the UN SDG to be achieved by 2030. The SDG positions health as a key feature of human development in a more integrated manner than was the case for the MDG. Certain important health issues that were not addressed in the MDG now have targets in the SDG, such as mental health, substance abuse, health impact from hazardous chemicals, water, and soil pollution and contamination and the effective implementation of the WHO FCTC (UN 2018c).

By the start of the twenty-first century, several series of analyses of the impact of rapid globalization on public health are available in many health and development literature. They all revealed that the global trade, finance, information and people flows, governance, and security could contribute to

improving the health of people everywhere. The threats to and opportunities in public health, including cross-country control of infectious diseases and international governance, have been analysed extensively within the context of globalization (Fidler 2004). An updated version of IHR is a guide for all countries to prevent, protect against and control, and provide a public health response to the international spread of a disease or diseases, in various ways that are commensurate with and restricted to public health risks, and that avoid unnecessary interference with international traffic and trade. The UN SDG outline the need to support countries to detect and manage health risks, build resilient health systems, and focus on protecting the most vulnerable populations.

Addressing healthy ageing

Many LMICs have experienced an expansion of the proportion of people above 60 years of age, from 1.2 billion in 2015 to 2 billion in 2050. They have started paying attention to dealing with older people's health by adopting appropriate comprehensive national policies and related legislation. They have focused on creating closer linkages between social welfare and health, providing care at home and in the community, promoting traditional family ties, optimizing the use of existing healthcare delivery systems and setting up elderly care homes. Access to essential healthcare for older people is still inadequate in many LMICs, since knowledge and skill among health and social workers for specific needs of older people is minimal. The economic, social, and health status of the fast-growing elderly population in LMICs poses a great challenge to all sectors.

Looking ahead

LMICs have undertaken a series of health reforms by improving the content of essential health packages and introducing a new way of financing. Many health financing models either at national or local levels were developed, including reforms in expanding social health insurance. Another global trend in health development is the increasing role of the private sector, both for-profit and non-profit. It is not a simple solution that can fit within a country's existing socioeconomic, political, and health situation. The extent of the

national health plans ensures that wider reforms would address the gaps in healthcare and create a pro-poor health system.

A multiplicity of new actors in national and international health arena had redefined the boundaries of the health sector. Groups of individuals, united to a particular cause, such as patient groups or civil societies both at national and international levels, have become major players for policy and programme development in public health by creating powerful lobbies and raising public awareness. A new paradigm in health development, in countries that must rely heavily on external aid for health in earlier years and even now, has led to a complex relationship among traditional and new players in international health and health-related development, for effective planning and use for resources, and the need for delineation and harmonization of responsibilities.

Conclusion

The history and development of public health in LMICs shows that important breakthroughs in public health interventions have led to great improvements in economic development. Health determines economic productivity and prosperity, and the physical and emotional well-being of the people. The mindset of the population afflicted with a high infant mortality rate usually lacks the secure knowledge of its children's longevity, witnesses higher fertility rates, and experiences the quality-quantity trade-off in child-rearing. Ever since the health-for-all movement was initiated over three decades ago, health, equity, and social justice remain the main themes of social and health policy. It is essential for all public health professionals to sustain these values, especially those in LMICs and the international community.

1.4

Public health priorities in countries undergoing economic transition

The middle-income countries

Stephen Tollman and Jessica Price

Introduction

Sustainable Development Goal (SDG) 3 highlights the range of health challenges which continue to reduce quality of life, extending the horizon of global health well beyond maternal and child health, HIV, and malaria—which dominated the Millennium Development Goals—to include non-communicable diseases, mental health, injuries, and exposure-related illnesses. SDG 3 further addresses the goal of universal health coverage (UHC) (World Health Organization n.d., b). However, if SDG 3 targets are to be met, the complex health challenges accompanying social and economic transitions in middle-income countries (MICs) must be confronted.

MICs are diverse in geography, population size, politics, and economic activity. The World Bank defines lower MICs as countries with a gross national income (GNI) per capita of $1,006 to $3,955 (currently 47 countries), and upper middle-income economies as those with a GNI per capita between $3,956 and $12,235 as of 2018 (60 countries) (The World Bank in Middle Income Countries 2018).

MICs are of special interest to public health researchers, practitioners, and policy makers first, because of the sheer number of people living in them—5 of the world's 7 billion; second, because despite rapid economic growth, many MICs remain highly unequal—reflected by a high GINI index and widespread persistent poverty; and third, because prolonged economic and social transitions drive a series of health transitions. These in turn put a premium on adaptive health systems able to respond to changing health needs (The World Bank in Middle Income Countries 2018).

Economic transition refers to structural, organizational, and institutional changes in national economies that affect their growth paths, policy context, and private sector evolution. Changes to the job market include growing numbers of skilled jobs and a rise in women's participation in the formal economy (with a move from unpaid home and care work to paid formal employment), increased labour-related migration, the establishment of new microeconomies, and rising expectations of standards of living, government services and social protection (International Monetary Fund 2000). Economic transitions are broadly separated into those required to boost countries from low- to middle-income (industrialization, greater privatization, movement to market-based economies); and transition from middle-income to high-income (characterized by a move from industrial to knowledge-based economies). Countries which transition successfully to middle-income, but fail to transition to high-income nations are said to be caught in a 'middle-income trap'. This describes the slowing of economic growth in MICs that are unable to develop new growth models and institutions required to drive knowledge-based economies (Gill and Kharas 2007). The 'middle-income-trap' is an important reminder that despite being described as linear processes, economic transitions are typically prolonged, heterogenous and non-linear with some countries even regressing to a lower income status—as in Argentina which was classified as high-income in 2014 and 2018, but as upper middle-income 2015–2017 and again in 2019 (World Bank 2019).

The upstream changes associated with economic transition lead to far-reaching behavioural transitions which feed through to health, risk and disease profiles—outcomes directly influenced by greater urbanization, changes in diet and physical activity, as well as educational and infrastructure development. Economic and social transitions have important downstream health system effects: management of diseases improve as numbers of health professionals increase with the upskilling of the population, and increased spending on healthcare as gross domestic product (GDP) grows. Positive effects on the social determinants of health include better female education, improvements in sewage and hygiene, and introduction of social protection policies—accompanied by declining maternal and child mortality, and infectious disease. However, offsetting impacts on health arise from overcrowding, air pollution, physical inactivity, alcohol and tobacco consumption, and high fat, sugar and salt diets often linked with hyperaccessibility to 'fast foods' (Miranda et al. 2019). This tends to manifest in growing

burdens of non-communicable diseases: diabetes, cardiovascular and respiratory diseases, and cancers. These changes in disease burden have been termed health transitions (Beaglehole and Bonita 2004).

In this chapter we start by reviewing the relationship between the economy and health, looking at changes in health outcome as income increases, demographic transitions related to economic growth, and the impact of urbanization on health outcomes. We then review major health challenges facing MICs, including the triple burden of disease, multimorbidity, mental health across the life course and the impacts of migration, climate change, and antimicrobial resistance. Finally, we discuss health system challenges and the importance of building resilient and 'learning' health systems with the agility to adapt to meet MICs' evolving health needs. We discuss strategies to achieve universal health coverage in MICs and the importance of intersectoral collaboration in promoting health. The key messages are outlined in Box 1.4.1.

Box 1.4.1 Key messages

1. MICs are countries undergoing social and economic transitions, which can be prolonged and non-linear.
2. Economic and social transitions have profound effects on the health burdens and related health behaviours in MICs. This is compounded by greater vulnerability to health impacts from climate change, migration, and antimicrobial resistance.
3. MICs are best served by resilient and 'learning' health systems, able to respond with agility to the changing health needs of the population.
4. Policies designed to enable universal health coverage and intersectoral collaboration can position MICs to meet the complex health needs of their populations.

Health and the economy

Income and health

Growth in per capita GDP is associated with improved health outcomes at a national level. This association was described by Samuel Preston in 1975, who showed that life expectancy at birth was higher in wealthier nations, but that the relationship flattens at higher incomes (Preston 1975). As shown in Figure 1.4.1 using 2012 data, in countries with a GDP per capita of up to ~$4,000 small increases in gross domestic product (GPD) are associated with large increases in life expectancy. At higher levels of GDP per capita the association weakens (Biciunaite 2014). Rising GDP per capita is also associated, in aggregate, with declining neonatal, infant and under-5 mortality (Pritchett and Summers 1993). As income rises and under-5 mortality falls, neonatal deaths typically account for a greater proportion of all under-5 deaths.

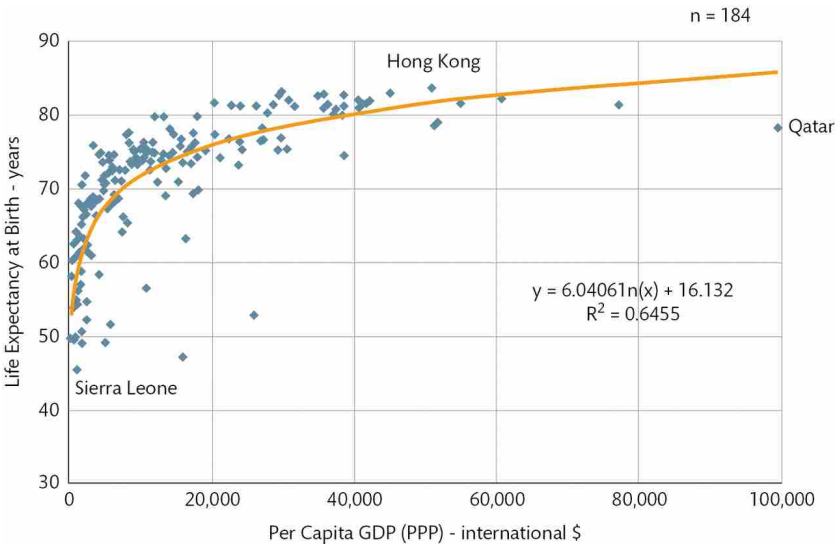

Fig. 1.4.1 Preston curve 2012: change in life expectancy at birth by per capita GDP (from Euromonitor International). Note: GDP based on purchasing power parity (PPP) and takes account of differences in pricing between countries.

©Euromonitor.

While the relationship between income and health outcomes holds across countries, national averages can mask significant differences in outcomes between the wealthy and the poor within the same country. This is especially problematic in MICs, many of which remain highly unequal. A recent review found that in India, a child in the poorest socioeconomic quintile is over 2.5 times more likely to die as one from the wealthiest quintile, with a difference in the under-5 mortality rate of over 30/1,000 live births. The ratio of under-5 mortality in the poorest quintile compared to the wealthiest in Brazil exceeded 2.5, and is above in South Africa (Chao et al. 2018). Table 1.4.1 illustrates differences in infant and child mortality by socioeconomic quintile for selected MICs where Demographic and Health Survey (DHS) data is available (World Health Organization, n.d., a; Hosseinpoor et al. 2016).

Table 1.4.1 Infant and under-5 mortality by socioeconomic quintile for selected MICs

Country	Year	Infant mortality (per 1,000 live births)					Under-5 mortality (per 1,000 live births)					GINI index (year)

Income and demography

In essence, demographic transition can be understood as a change in population dynamics from high mortality and birth rates (fertility), to low mortality and fertility as socioeconomic development (notably female education) occurs. The demographic transition results in changes to population age structure, with implications for labour capacity, child and older adult dependence, and disease and disability burdens (Coale 1989).

As a group, MICs span multiple stages of demographic transition (Table 1.4.2): those at an earlier stage of transition experience a growing proportion of young people in the population; while at later stages, fertility declines and population size stabilizes. Concurrent declines in mortality and fertility can produce a 'demographic dividend' with greater productivity of adults in the labour force resulting from fewer child dependents (so a decline in the dependency ratio) (United Nations Population Fund, n.d.). A greater proportion of economic resources can therefore be invested to speed development. However, the benefits of a demographic dividend are not guaranteed: in addition to education and health systems to support more productive working populations, the demographic dividend requires a buoyant economy that can withstand shocks. In contrast, in countries with high youth unemployment, economic growth remains slow even as the dependency ratio falls (Table 1.4.2). In addition, where economic benefit is realized, this can be short-lived: as the population ages greater care burdens are place on the state and on working adults to care for older generations. Growth in the population 65 years and older results in a rise in the old-age dependency ratio and is generally associated with a slowing of per capita income growth (United Nations Population Fund n.d.).

Although characterized as a linear transition with sequential stages, the reality of demographic transitions in MICs is generally more complex. In southern and east Africa, the HIV epidemic resulted in rising mortality in the 1990s and early 2000s despite a continued decline in fertility. AIDS-related mortality mostly affected adults age 30–44 (i.e. the working generation) resulting in significant burdens placed on older persons to take over the roles of primary caregiver and breadwinner (with households increasingly dependent on old-age pensions as sources of income) (Hosegood et al. 2007). Although demographic transitions tend to accompany economic transition, it is possible for demographic transitions to continue despite economic stagnation.

Table 1.4.2 provides trend data for selected MICs from 1997 and 2017, demonstrating the heterogeneity of demographic transitions across countries.

Urbanization and health

Urbanization is arguably the most ubiquitous and powerful social transition with mixed effects on personal and population health. On one hand, given the concentration of services, urbanization can support marked health gains through improved access to education, healthcare, and employment. However, when urbanization occurs in a rapid, unplanned, and uncontrolled manner—as seen in the creation of urban slums—urbanization itself can become a risk factor for poor health outcomes (Patil 2014).

Urban slums are overcrowded with a lack of proper hygiene and sanitation systems, informal housing, and unreliable water and energy supply. While some slums have a quasi-permanent character, others have high turnover of residents (Ezeh et al. 2017). As a result of poor living conditions, slum-dwellers are at risk of infectious diseases such as TB, acute respiratory infections, diarrhoea, and vector-borne diseases including malaria (Elsey et al. 2019). Conditions of poverty including a lack of food put children of the urban poor at increased risk of undernutrition and stunting (Patil 2014).

Behaviour changes influenced by urbanization include dietary preferences, tobacco, and alcohol consumption and physical activity—contribute at population level to a rising incidence of non-communicable disease and risk including obesity, hypertension, diabetes, and cardiovascular disease. Urbanization has also been shown to negatively affect mental health—with increasing stress and social isolation, and higher levels of violence and injury (Patil 2014). Changes in household structure—tending to more households of smaller size occur in rural and urban areas (Wittenberg et al. 2017) and exacerbate the loss of social support (Patil 2014).

Increasing pace of migration—whether unidirectional or circular—of sizeable numbers to cities increases demands on transport and leads to more (often less roadworthy) vehicles. Furthermore, vehicles in low- and middle-income countries are typically more polluting than those in high-income countries (HICs). Combined with rapid industrialization, this contributes to worsening air pollution[1] which in turn may exacerbate chronic respiratory conditions and contribute to cardiovascular events and cancers. In 2018, air pollution was assessed the fifth leading risk factor for death globally, and the third and fourth leading risk factor for mortality and disability-adjusted life years (DALYs) combined in India and China respectively (Institute for Health Metrics and Evaluation (IHME) 2018; Institute for Health Metrics and Evaluation (IHME) 2018b; Health Effects Institute 2019).

Finally, urbanization is associated with localized rises in temperature relative to surrounding areas—known as the 'Urban Heat Island' effect. This results from increased heat production, reduced surface evaporation, changing thermal characteristics and rising air pollution (Grover and Singh 2015). The negative impacts of rising temperatures, including heat stroke, cardiovascular and respiratory mortality, are discussed in the following section on climate change and health.

[1] Air pollution is measured using particulate size >25 µm (PM2.5). Over the past 30 years, PM2.5 concentrations have increased by ~25% across South Asian cities. Furthermore, growth of urban populations means more people exposed to harmful levels of air pollution (Miranda et al. 2019).

Health challenges in MICs

Triple burden of disease

The triple burden of disease describes the concurrent, often interacting health burdens of (1) communicable, maternal, neonatal, and nutritional disease (CMNN); (2) a rising burden of non-communicable disease; and (3) substantial morbidity and mortality from injuries.

As seen in Figure 1.4.2, non-communicable diseases (NCDs) are now the leading cause of death and account for the largest proportion of DALYs globally and in MICs (Institute for Health Metrics and Evaluation (IHME) 2018c). This reflects changes in the social determinants, risk factors, and behaviours associated with the economic and social transitions occurring in MICs, as well as the impact of demographic transitions—with growing proportions of the world population over 65 years (Table 1.4.2). According to figures from the Global Burden of Disease study, stroke, ischaemic heart disease, chronic obstructive pulmonary disease (COPD), and lung cancer were leading causes of DALYs in China in 2017. This marks a significant change from 1990 when lower respiratory infections and neonatal disorders were first, followed by stroke and COPD (Zhou et al. 2019). In India, leading causes of death in 2017 were ischaemic heart disease, COPD, and stroke (IHME 2018); and in Mexico ischaemic heart disease, chronic kidney disease, and diabetes remained the leading causes of death from 2007 to 2017 (IHME 2018d).

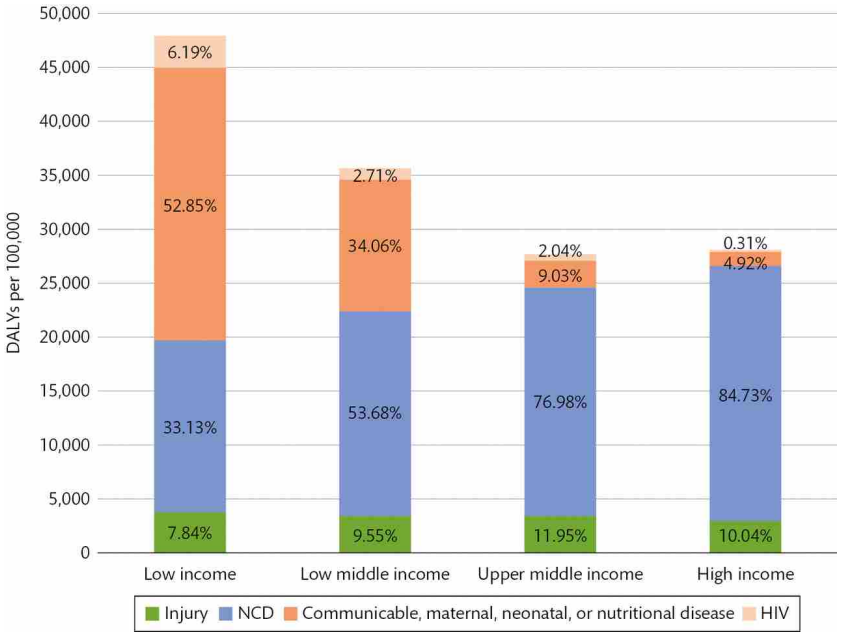

Fig. 1.4.2 Causes of DALYs across World Bank Income groups, 2017.
Data from Global Burden of Disease study 2017 (IHME 2018c).

However, MICs continue to face a substantial burden from infectious disease, maternal, neonatal, and nutrition-related conditions (Fig. 1.4.2) (Bawah et al. 2016; IHME 2018c). This despite improvements in hygiene and sanitation, declining fertility rates, greater female education, and targeted interventions resulting in increased vaccination rates, skilled birth attendants at delivery and the use of artemisinin-based treatment for malaria among others. Furthermore, there is growing recognition of the interaction between infectious and NCDs, especially cancers (e.g. human immunodeficiency virus and Kaposi's sarcoma as well as lymphomas, human papilloma virus and cervical cancer, and chronic hepatitis B infection and liver cancer).

Finally, injuries (from road traffic accidents, interpersonal violence, homicides, and self-harm) continue to account for approximately 10% of the global burden of disease and the same is true in MICs (Fig. 1.4.2). However, the impact of DALYs from injuries are disproportionately felt in MICs (and low-income countries) where car ownership is rising rapidly, preventive strategies are less developed, traffic and alcohol regulations are poorly enforced and health systems are less prepared to manage injury emergencies (Gosselin et al. 2009).

South Africa—along with many countries in southern and eastern Africa—is described as having a quadruple burden of disease (Groenewald et al. 2017) so recognizing the impact of HIV and TB. HIV/AIDS remains the leading cause of death in South Africa in 2017, as well as the leading cause of premature death and disability (IHME 2018f).

The complexity of disease burdens facing MICs is also reflected by the concurrence of risk factors that promote both communicable and non-communicable disease. This is best highlighted by the coexisting epidemics of underweight and overweight populations within the same country (Manyanga et al. 2014; Ford et al. 2017). Furthermore, both epidemics are typically experienced by the poorest socioeconomic quintiles, with wealthier quintiles having better health outcomes across all risk factor and disease groupings. In addition to changing nutritional patterns—driven in part by the expansion of multinationals into MICs and the hyperaccessibility of 'fast foods' (Miranda et al. 2019)—increased consumption of tobacco and alcohol, high blood pressure, raised glucose and air pollution are among the leading risk factors contribution to DALY's across the BRICS nations and many other MICs (IHME 2018; IHME 2018a, 2018e, 2018b, 2018f).

Multimorbidity

A consequence of these complex, sometimes interacting infectious, non-communicable and injury-related disease burdens, is the growing challenge of multimorbidity—referring to the presence of two or more chronic conditions in the same individual (Academy of Medical Sciences 2018). Increasingly individuals in MICs have coexisting conditions which manifest at younger ages. Thus multimorbidity is not only due to population ageing, but also

because of the premature growth in prevalence of NCDs, and persistence of communicable disease including HIV and TB (Academy of Medical Sciences 2018). See Box 1.4.2.

Box 1.4.2 Multimorbidity

Multimorbidity refers to the coexistence of two or more chronic conditions, each one of which is either:

- A physical non-communicable disease of long duration, such as a cardiovascular disease or cancer.
- A mental health condition of long duration, such as a mood disorder or dementia.
- An infectious disease of long duration, such as HIV/AIDS or hepatitis C.

The World Health Organization (WHO) Study on global AGEing and adult health (SAGE)—which considered non-communicable conditions in China, Ghana, India, Mexico, Russian Federation and South Africa—found that NCD-related multimorbidity affected 19% of the adult population (compared to 17% with only one NCD). Furthermore, 17.43% of 18–49 year olds already had 1 NCD with 9.27% having two or more NCDs. This burden only grows as the population ages: a third of 50–64 year olds had two or more NCDs (Sum et al. 2019).

Though recognition of the impact of multimorbidity on treatment requirements, patient outcomes, and health system demands is growing, there remains limited evidence about the most common clusters of chronic conditions and the relevance of the different combinations. In attempting to group coexisting conditions, those which are similar in their origin and/or treatment requirements have been termed concordant multimorbidities (e.g. ischaemic heart disease and stroke are both related to hypertension), while those which differ in their origin and treatment are classified as discordant multimorbidities (e.g. ischaemic heart disease and depression) (Academy of Medical Sciences 2018). Contrasting patterns of multimorbidity have also been described, a European pattern reflecting combinations of two or more NCDs (that may be similar to China, South Asia, and South America), whereas multimorbidity patterns including HIV/AIDS or TB and non-communicable disease is common in African settings. Successful antiretroviral treatment programmes and subsequent rise in life expectancy of people living with HIV means that multimorbidity including HIV/AIDS will become more prevalent (Bawah et al. 2016).

There is evidence to suggest that the different chronic disease dyad and triad combinations have different health system implications; for example, patients with multimorbidity including depression having fewer outpatient visits but more hospitalizations and generally reporting a lower quality of life (hypothesized to result from limited use of primary care services and delayed presentation to more specialized care leading to hospital admission (Sum et al. 2019)). Work from South Africa suggests that HIV positive patients on antiretroviral therapy (ART) have better outcomes across a range of coexisting conditions including better blood pressure control and lower blood glucose. The ‘ART advantage’ is thought to arise through increased healthcare utilization in people living with HIV/AIDS (Manne-Goehler et al. 2017; M’yambo Magodoro et al. 2019).

However, the health system implications of multimorbidity extend beyond utilization rates: these patients contribute to an excessive workload and cost (beyond simply the sum of treating the individual conditions). Vertically designed programmes tend to be specialized and may miss opportunities to manage concurrent conditions—though further data is needed to assess the contrasting impacts of vertical, horizontal, and diagonal health system designs (Academy of Medical Sciences 2018).

The impact of ART on life expectancy is resulting in rising prevalence of HIV/AIDS in ageing populations also at risk of other chronic NCDs (Bawah et al. 2016; Chang et al. 2019). The implications of managing patients’ concurrent HIV and NCD treatment needs demand greater consideration, particularly in southern and eastern Africa which account for almost 60% of all people taking ARVs globally (Chang et al. 2019).

Finally, despite evidence that multimorbidity and associated risk affects both adolescent and ageing populations, most health systems are poorly configured to meet the needs of these key groups. Notably, in adolescents, emphasis on preventive strategies and behaviour change interventions will be required (e.g. promoting healthier lifestyles and reducing obesity which will pay dividends later in life) (Patton et al. 2016).

Mental health across the life course

The burden from mental, neurological and substance use disorders continues to grow globally, in part reflecting demographic and epidemiological transitions as well as greater awareness. Mental health across the life course is a particular concern for MICs as known social determinants of mental illness and substance use disorders include

inequality, poverty, childhood adversity, displacement, and violence (Patel et al. 2018). As such, mental health status is an important pathway in the cycle of intergenerational poverty (Fig. 1.4.3) (Leon and Walt 2000; Patel et al. 2018).

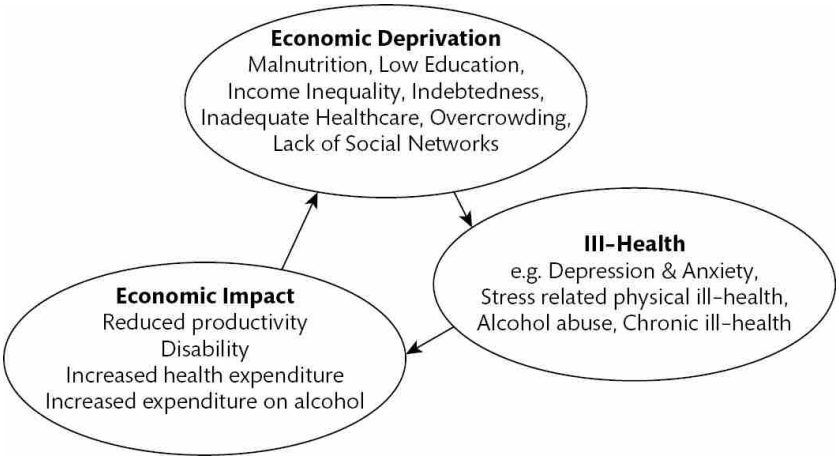

Fig. 1.4.3 The cycle of poverty and mental illness. From poverty, inequality, and mental health in developing countries (2000).
Reprinted from Leon, D. A. and Walt, G. (2000) 'Poverty, inequality, and mental health in developing countries', in Leon, D. and Walt, G. (eds) *Poverty, Inequality, and Health*. Oxford University Press, with permission from Oxford University Press.

A life course approach highlights critical periods which increase the risk for mental ill-health and require multilevel preventive and treatment strategies (Patel et al. 2018). Similarly, the concept of allostatic load (McEwen and Seeman 1999) recognizes the impact of cumulative psychosocial stresses which in turn lead to physiological 'wear and tear' contributing to negative health outcomes, including poor mental health.

Childhood experiences of early life stresses associated with low socioeconomic status and lack of stimulation in infancy are shown to increase the risk of mental health problems in later life. The presentation of mental disorders in adolescents is partly explained by the centrality of peer opinions which tend to replace those of parents and family and can be influenced by complex patterns of brain and cognitive development (Patton et al. 2016). This is a challenge in MICs where health systems seldom meet the health needs of adolescents despite growing adolescent and young adult populations. In older adults, mental health outcomes often relate to earlier life experiences, and a lack of formal education increases the chances of cognitive decline. Furthermore, cognitive impairment is associated with depression over the life course and so societies more exposed to risk factors for depression may experience increased burdens of dementia as populations age, a concern for MICs (Patel et al. 2018).

In addition, significant treatment and care gaps exist and surveys from China and India suggest that over 80% of people with a mental or substance use disorder did not seek treatment (Wei et al. 2013; Murthy 2017). Lack of access to care partly reflects underspending on mental health, with MICs spending approximately 2% of health budgets on mental health despite mental illness accounting for almost 30% of DALYs. Furthermore, most of this is spent on tertiary centres and inpatient institutions with little investment in community-based and primary care interventions (Patel et al. 2018).

Quality of services also tends to be poor: the World Mental Health Surveys report that only 11.4% of patients living with major depressive disorder in upper MICs receive minimally adequate treatment, and this drops to 3.7% in lower MICs (Thornicroft et al. 2017). Regarding substance use disorders, only 4.3% of patients in upper MICs and 1% of patients in lower MICs receive minimally adequate treatment (Degenhardt et al. 2017).

Migration

Most global migration occurs within LMICs (Abubakar et al. 2018). There were an estimated 258 million international (cross-border) migrants in 2017 (UN Department of Economic and Social Affairs Population Division 2017). However, internal migration—referring to movement within national borders—accounts for far more movement globally with over 740 million internal migrants in 2009 (four times the number of international migrants in the same year) (UNDP 2009). Internal labour migration may be from rural to urban areas (accounting

for much of urban growth in MICs), or from rural to rural areas based on work opportunities in agriculture or mining (with the proportion of female migrants growing substantially in recent decades. Importantly, evidence is strong that labour migrants, whether international or internal, generally contribute positively to a host country's economy. There are also consistently more internally displaced people in LMICs (due to conflict or natural disasters) than refugees or asylum seekers (being forced international migrants) (Abubakar et al. 2018). While it remains challenging to assess the full range of migrant health needs due to limitations in data quality, migration should be recognized as a core determinant of health in MICs.

The UCL-*Lancet* Commission on Migration and Health (2018) highlighted that migration is rarely a single journey (Abubakar et al. 2018)—with patterns involving variable distances within and across borders, temporarily or permanently, and often multiple times. Migration may involve several phases (Fig. 1.4.4) (Abubakar et al. 2018), each of which poses particular health risks relevant to planning health systems in MICs. Health of individuals pre-departure may be poor; the mode of transport can pose risks of injury or exposure, as can environmental and pathogen exposures on the journey. In the new country or region of residence, migrants face different infection and occupational exposures. And when returning to their origin home, the health risks may increase—some having lost immunity to local pathogens or having returned home following injury or disability without being able to access the necessary services (Abubakar et al. 2018).

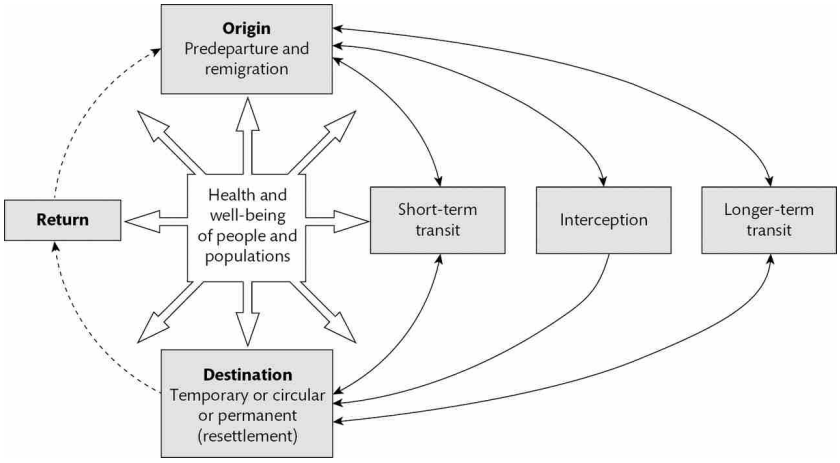

Fig. 1.4.4 The migration cycle.
Reprinted from Abubakar A et al. (2018) 'The UCL-*Lancet* Commission on Migration and Health: the health of a world on the move'. *The Lancet* 392(10164):2606–54, with permission from Elsevier.

Mortality rates among migrants have been studied in various settings. While a 'healthy migrant effect'—whereby health among migrants tends to be better than expected with lower risk for disease—the theory overlooks the diversity among migrant groups, and that the health benefits of migration may reduce over time. Data on mortality among migrants in MICs is limited however work in sub-Saharan Africa concluded that internal migrants often display higher mortality than long-term residents. This health disadvantage arose due to both infectious and non-communicable disease, and was likely linked to poor social integration and access to care, and inadequate living conditions (Abubakar et al. 2018; Ginsburg et al. 2018).

Evidence on the relationship between migration and mental health is mixed: international migrants, particularly asylum seekers and refugees, tend to have higher rates of depression, anxiety, and post-traumatic stress disorder. This often reflects differences in the precipitating risk factors such as experience of violence and traumatic events (Patel et al. 2018). The economic and psychosocial stresses of migration and urbanization may place migrants at greater risk of poor mental health outcomes (Ginsburg et al. 2018). Finally, migration appears linked to mental health outcomes in children: both in children who migrate, where research suggests they are more likely to have depression, anxiety, aggression, or hyperactivity, and among children left behind. A meta-analysis of studies on left-behind children suggested they are at increased risk of depression (RR 1.52, 95%CI 1.27–1.82), anxiety (RR 1.85, 1.36–2.53), substance use (RR 1.24, 1.00–1.52) and suicidal ideation (RR 1.70, 1.28–2.26) (Patel et al. 2018).

In South Africa, internal ‘circular’ labour migration—whereby workers move to town but maintain regular contact with their rural home—was an important factor in propagating the HIV epidemic: migration led to an increased risk of HIV infection, though acquisition and transmission could be bidirectional, e.g. from migrants to their rural partners, and from rural residents to their migrant partners (Lurie et al. 2003). As migrant labourers developed AIDS (or other serious chronic condition), becoming too sick to work, they chose to ‘return home to die’ (Welaga et al. 2009), with significant attendant care burdens and health-related costs borne by their households during their final stage of illness.

As a principle, consistent with the goal of UHC, health systems need to incorporate the competencies required to address the specific health needs of the migrant population, whether citizens or not. Furthermore, health systems need to strengthen their capability to provide services to highly mobile groups unlikely to access care from the same place consistently over time.

Climate change and health

MICs include countries heavily affected by climate change through altered temperature and rainfall patterns coupled with extreme weather events resulting in widespread health, social, and economic impacts. MICs are at risk of climate-related health effects for three reasons: (1) geography viz. a higher concentration of heatwaves, adverse weather events such as droughts and floods, and loss of labour capacity especially in areas close to the equator; (2) national systems lack the resilience needed to adapt to persisting weather changes, respond to disasters, or diversify food sources—with single crop markets at particular risk; (3) less developed regulatory frameworks to limit key drivers of climate change such as fossil fuels, and provide incentives for clean energy.

Climate change has both direct and indirect health impacts. Direct effects include exposure to heat waves and rising temperatures, as well as weather-related disasters. Indirect effects are those mediated through changes in ecosystems, land use, air pollution and water quality (Fig. 1.4.5).

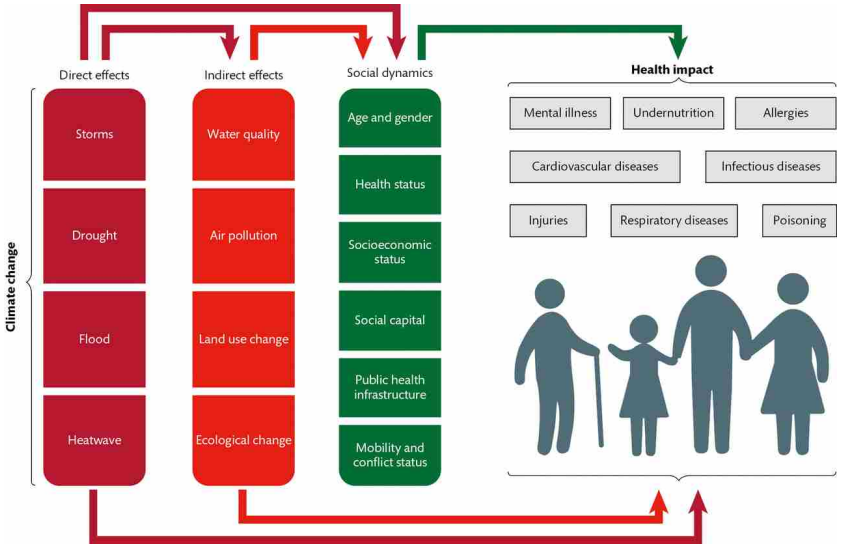

Fig. 1.4.5 The direct and indirect effects of climate change on health and wellbeing. From *Lancet* Commission on Health and climate change: policy responses to protect public health.

Reprinted from Watts, N., *et al.* (2015) ‘Health and climate change: policy responses to protect public health’, *The Lancet*. 386(10006), pp. 1861–914, with permission from Elsevier.

Direct health effects

Increased temperature and heatwaves can exacerbate chronic conditions, lead to new cardiovascular and renal conditions, and provoke dehydration—to which older persons are especially prone. Furthermore, when combined with urbanization and air pollution, not only is the temperature rise amplified, but acute and chronic respiratory disease tends to worsen (Watts et al. 2015).

The impact of heat exposure is also evident in the fall in outdoor labour productivity (some 5.3% decline worldwide 2000–2016—with the greatest reductions in countries worst affected by rising temperatures, many of which are MICs). The decline in outdoor labour productivity is paralleled by both a rise in health burden and reduction in economic output—of particular concern for MICs where much of the labour force continues to work in industry (Watts et al. 2015, 2018).

Concern around climate-sensitive diseases is growing: greater exposure to UV rays resulting from damage to the ozone layer is leading to rising incidence of malignant melanoma (Watts et al. 2018); and climate-related weather disasters result in direct morbidity and mortality, and can cause mental health disorders linked to the trauma of the extreme weather events (Watts et al. 2015).

Indirect health effects

Most climate-related health risks are mediated through ecological and social processes. Food insecurity is among the greatest impacts of climate change and arises through multiple pathways including crop failure, reduced food production, extreme weather events, increased food-borne and other infectious diseases, and civil unrest. While severe food insecurity and hunger are associated with undernutrition, wasting, and stunting in children, mild to moderate food insecurity has been associated with obesity in vulnerable populations (Swinburn et al. 2019), a paradox of concern in the context of high inequality and rising NCDs in MICs.

Diseases related to water quality (e.g. cholera) and vector spread (including malaria and dengue fever) are impacted by rising temperatures and changes in rainfall patterns. Warmer temperatures promote cholera bacterial growth, while droughts and extreme weather events can limit access to safe drinking water. In areas previously protected by lower temperatures, climate change is affecting the range and reproductive rate of malaria-carrying mosquitoes, even at higher altitudes, with growing risk of new malaria epidemics (Watts et al. 2015). This increase in vector capacity also contributes to the climbing incidence of dengue fever with an estimated 58.4 million cases in 2013 (95%CI 23.6 million –121.9 million) accounting for some 10 000 deaths and 1.14 million DALYs. Much of this burden is in the Asia-Pacific, Latin American and Caribbean regions—mostly MICs. The *A aegypti* and *A albopictus* mosquitoes which transmit dengue are also vectors for emerging and re-emerging arboviruses including Yellow Fever, Chikungunya and Zika virus (Watts et al. 2018).

Antimicrobial resistance

MICs face a paradox when it comes to antimicrobial use: on one hand, infections continue to account for a significant burden and are the leading cause of death in some countries, notably in children under-5. An estimated 445, 000 pneumonia-related child deaths could be averted through universal provision of antibiotics (Laxminarayan et al. 2016). On the other hand, antimicrobial resistance (AMR) is a growing problem, driven largely by increasing and inappropriate use of antibiotics (Miller-Petrie et al. 2018). With regard to neonatal mortality alone, resistant sepsis infections kill approximately 214, 000 neonates each year primarily in India, Pakistan, Nigeria, the Democratic Republic of Congo, and China (four of these five countries are MICs) (Miller-Petrie et al. 2018).

Tackling antimicrobial resistance in MICS is challenging for several reasons:

Increasing consumption of antibiotics: although per capita antibiotic use remains lower in MICs than HICs, MICs saw the highest growth rates in antibiotic consumption 2000–2010 and have higher drug resistance indices (Klein et al. 2019). In part this is due to rising income and greater access to antibiotics, however, it also reflects supply-side problems including: lack of enforcement of prescribing regulations, high rates of over-the-counter purchasing, and a lack of incentives for rational prescribing, all of which lead to inappropriate antibiotic use. Substandard and falsified medications are also a concern; while this is common in India, the WHO estimates that it affects 7% of antibiotics globally (Miller-Petrie et al. 2018; World Health Organization 2018b). Lastly, changing patterns of antibiotic use have resulted in increased consumption of broad-spectrum antibiotics including cephalosporins, broad-spectrum penicillins, and fluoroquinolones, as well as increased use of last-resort antibiotic classes (carbapenems and polymixins) (Laxminarayan et al. 2016).
Antimicrobial use in animals: two-thirds of all antibiotic use, including antibiotics to treat infections in humans, are used in animals at subtherapeutic levels to promote growth and prevent disease, and at therapeutic levels to treat infection in livestock (Laxminarayan et al. 2016). Estimated use of antibiotics in food production is expected to virtually double (98% increase) in BRICS nations (Brazil, Russia, India, China, South Africa) by 2030, including a projected 312% increase in India alone (Laxminarayan et al. 2016). Widespread use of antibiotics in farming creates strong selection pressure, encouraging the development of resistant infections (Miller-Petrie et al. 2018) which will have impact human and animal health (encompassed in the concept of One Health). However, few MICs regulate or monitor the use of antimicrobials in animals—or have adequate capacity to do so (Hu and O'Neill 2019).
Lack of antimicrobial resistance surveillance programmes: Accurate data on AMR is required to effectively design programmes to prevent the spread of infection and tackle inappropriate prescribing practices. However, few MICs have managed to establish routine antimicrobial surveillance systems. And where these do exist, data is usually publicized in annual reports of resistance profiles, making it difficult to respond rapidly to changes in resistance and outbreaks of resistant organisms (Perez and Villegas 2015). Furthermore, no AMR surveillance programmes in MICs include data on antimicrobial use and antibiotic resistance in agriculture and livestock (World Health Organization 2014). A global AMR surveillance system (GLASS) is being developed by the WHO to support the global action plan on antimicrobial resistance, and aims to improve surveillance capacity and data quality particularly in LMICs (World Health Organization 2018a).
Lack of data from primary care settings: Where data on AMR is available—whether from surveillance programmes or specific research studies—this tends to focus on resistance in hospital settings and is extrapolated to estimate the community prevalence of AMR (World Health Organization 2018b). However, the impact of antibiotics used in farming and the environment, substandard and falsified medications, and self-medication with antibiotics are more likely to affect community-acquired infections. Most patients with bacterial infections sensitive to first line antibiotics will improve with treatment at primary care level and not present to higher levels of care. As a result, extrapolating trends in AMR from hospital level data could over- or underestimate AMR in the community, and resistant strains may vary between hospital and community settings.

The consequences of AMR can be more severe in MICs (and low-income countries (LICs)) than HICs. Mortality from resistant infections may be higher—due to a lack of access to newer and more effective drugs, compounded by poorer social determinants of health (World Health Organization 2018b). Where second- and third-line drugs are available they tend to be more expensive: the World Bank estimates that AMR could push 28 million people into poverty by 2050 (World Bank 2017). Furthermore, the growth of fluoroquinolone resistance is of particular concern as fluoroquinolones are used in the treatment of multidrug resistant TB which remains a priority in many MICs (Hu and O'Neill 2019).

Finally, strategies to limit AMR include preventing infection with regular hand washing and infection control in health facilities (Miller-Petrie et al. 2018), practices which tend to be less well implemented in MICs compared to HICs. Similarly, vaccinations can protect against common infections, reducing the need for antibiotics (Miller-Petrie et al. 2018). However as MICs graduate from GAVI, the Vaccine Alliance, they will need to take on higher vaccine costs—as of December 2020 only India, Nigeria and Indonesia will remain eligible for assistance out of the nine BRICS and MINT (Mexico, Indonesia, Nigeria, Turkey) nations (Hu and O'Neill 2019).

Health systems in MICs

Given the complex and heterogeneous health challenges facing MICs as a consequence of the evolving, dynamic transitions underway, it is critical that health systems in these countries adapt to respond to societies' changing

health needs. This cannot be achieved by simply improving the efficiency of current approaches; rather it requires an all-round rethinking of health systems in these settings, taking cognisance of inevitable resource constraints. We suggest the following tenets underpin future-oriented health systems in MICs—that they

be *resilient and learning health systems*
strive to provide *UHC*
focus on the *quality of health services* in addition to their availability
take into account the contributions possible from *intersectoral collaboration.*

Resilient and learning health systems

'Resilience' describes the degree to which health systems can absorb shocks and adapt to provide the required services (Kruk et al. 2015; Massuda et al. 2018). Although the phrase gained traction following the 2014–2016 Ebola crisis in West Africa, there is growing recognition of the importance of everyday resilience in resource-constrained health systems which experience repeated shocks (such as funding shortages, unreliable staffing, changing policies and guidelines, and growing administrative burdens) (Gilson et al. 2017; Massuda et al. 2018).

Resilient health systems can be characterized by five elements: (1) awareness of available assets and vulnerabilities (human, physical, informational); (2) capacity to address a diversity of health needs across communities (measured in part by the degree to which universal health coverage has been achieved); (3) self-regulation with the capability to rapidly identify and contain new health threats while continuing to provide other essential health services; (4) integration of health services with other sectors to maximize the innovation in solutions to health challenges (which requires clear communication and information sharing); (5) adaptation to meet new health needs, both in response to emergencies and slower changes in evolving disease burdens (Kruk et al. 2015).

A learning health system is also one which has as a central tenet, a focus on routinely collected data as a basis for continuous improvement integrated into the everyday functioning of services (English et al. 2016)—in this way, learning health systems can ore rapidly adjust their practices to adopt new evidence and improve the quality of patient care.

Both resilient and learning health systems depend on accurate and up-to-date data upon which to base decisions, evaluate progress, and adapt in response to available evidence. To-date, many MICs lack comprehensive civil registration and vital statistics (CRVS) systems. Investment in routine information systems is necessary as MICs endeavour to strengthen their health systems. Doing so as part of initial health system strengthening can prove far more cost-effective than retro-fitting data collection systems later (English et al. 2016).

Universal Health Coverage

In 2005, all WHO member states committed to working to achieve UHC, i.e. that all people are able to access high-quality health services when needed (including preventive, promotive, curative, rehabilitative and palliative services) without risk of financial hardship (WHA58.33 Sustainable health financing, universal coverage, and social health insurance 2005). UHC is a particularly powerful and unifying principle for health systems in MICs: systems designed around the provision of essential care to all regardless of citizenship, nationality, age, or gender should be far better placed to address the complex disease burdens and provide integrated care for patients with multimorbidity, often at young adult ages. UHC is also a critical element in strategies to better provide migrant health services by lowering barriers to care related to entitlement to use services, where and which services, and essential information sharing between providers when patients routinely do not attend the same clinic.

While few MICs can claim to have achieved UHC, some have made substantial strides as detailed in the World Bank's *Going Universal* report (Cotlear et al. 2015). Although approaches vary, key features include increased health spending, pooling of funds, decentralization of care management, effective private–public partnerships, and expansion of comprehensive primary care services (Cotlear et al. 2015; Castro et al. 2019). Box 1.4.3 details elements of the Brazilian effort to achieve UHC.

Box 1.4.3 Achieving UHC in Brazil

The basis of UHC in Brazil is the Sistema Unico de Saúde (SUS)—a unified health system established in 1990 following the enshrining of health as universal human right in the Brazilian constitution of 1988. SUS decentralized health programme financing and management, sharing power between

federal and municipal structures. All citizens are entitled to services provided by SUS, however the purchasing of private insurance by higher income groups means that SUS services are largely utilized by poorer and uninsured members of the population.

As explained by Castro and colleagues (2019), SUS changed the model of healthcare delivery, expanding comprehensive primary care services and investing in the Family Health Strategy (a community-level health delivery platform) which increased service provision from some 7 million people (4% of the population) in 1998, to 130 million people (62% of the population) in 2018. In addition, mental health services, emergency care services, and specialist outpatient services were developed. Private–public partnerships were established to boost access to specialist care whereby the public sector funds service and facilities, but management and staff are provided by the private sector (Castro et al. 2019).

The SUS is credited with significant improvements in health outcomes including rising life expectancy at birth, a fall in under-5 mortality from 64/1,000 live births in 1990 to 15/1,000 in 2015, and increased immunization coverage. SUS enabled Brazil to meet the rapidly changing health needs of its population, driven by migration from rural to urban areas, re-emerging infectious disease due to expanded human occupation of regions of the Amazon, rapid demographic and epidemiological transitions resulting in an increasing burden from non-communicable diseases (Castro et al. 2019).

However, Brazil also serves as a warning to MICs of the fragility of health gains, and the ease of reversal when political leadership changes and investment in health systems decline. Introduction of austerity measures in 2016, including capped increases in health spending, and changes to reproductive and adolescent health services which threaten to limit access to care (given fear of promoting abortion), failure to explicitly include the lesbian, gay, bisexual, transgender, and questioning (LGBTQ+) community in ministerial mandates (claiming instead that 'diversity policies have threatened the Brazilian family'), education policies which prevent teachers from discussing gender, identity, and sexuality, amendments to gun laws which will increase their availability, and possible reductions in tobacco taxation all threaten to reverse—at least in part—the hard won health gains of the past 30 years (Castro et al. 2019).

Although the principle of UHC is increasingly accepted, financing remains more controversial. The move towards UHC will see countries increase total health expenditure even in scenarios where there are significant efficiency gains. Ability to afford this increase is largely driven by economic growth and so increased available national income. However, in addition to increased spending, UHC requires pooled spending with criteria for contributions distinct from criteria for use (which is simply health need). Different strategies to pool spending are available (Schuster et al. 2018): some countries use general taxation; however, this can be challenging in countries with high unemployment and small tax bases (which may already be heavily taxed). Some countries have used compulsory payroll contributions (Hong 2009), while others have targeted public health insurance to the most vulnerable groups who do not meet criteria for employment-based schemes (such as the Seguro Popular programme in Mexico (Frenk et al. 2006)).

Countries also need to resolve what health services to fund (often referred to as a 'minimum benefits package'). This too will vary depending on what countries can afford. However, the Disease Control Priorities Project (3rd ed.) recommended standardized essential care packages that all countries should strive to provide based on value for money, disease burden and feasibility of implementation (Watkins et al. 2017).

There is ongoing debate on the extent to which migrants gain access to the various models of UHC emerging. Thailand is among the best-known examples of migrant-inclusive policies: migrants with work permits are fully covered by the Thai social security scheme which is funded through mandatory payroll taxes including contributions from the employer, employee, and government. However, the majority of migrants in Thailand are undocumented and so ineligible for social health insurance. Therefore, in 2001, Thailand established a migrant health insurance scheme which migrants (documented or not) could join through a voluntary annual prepayment premium. The scheme was later extended to cover migrants' dependents. Furthermore, Thailand invested in innovations to create migrant-friendly health services, including use of volunteer community workers to assist with health education, mobile clinics, and bilingual signposts. These efforts have served to increase access care for migrants, improve diagnosis and treatment, and reduce financial risk from large out-of-pocket payments, though work remains to increase the proportion of migrants enrolled (Tangcharoensathien et al. 2017).

Quality healthcare services

The quality of care is as important as the extent of care provided: the Lancet Global Health Commission on High Quality Health Systems in the SDG Era found that improving quality of care could save an estimated 8 million lives in LMICs each year. Furthermore, promoting quality care can be expected to increase patient trust and improve patients' experience of engaging the healthcare system (Kruk et al. 2018). However, health systems in MICs remain underresourced relative to the need and so innovative strategies are required to deliver quality care at an affordable cost. Task shifting and digital technologies are strategies increasingly used to extend high-quality healthcare in MICs.

Task shifting

Task shifting, an approach that is widespread in global health, refers to the process of redistributing tasks to less specialized healthcare workers (World Health Organization 2007) and was successfully employed at scale in response to the HIV epidemic in sub-Saharan Africa: counselling and testing 'shifted' from nurses to lay counsellors or community health workers (CHWs); treatment initiation and monitoring transferred from doctors to

nurses as did diagnosis and management of opportunistic infections; and management of advanced disease shifted from infectious disease specialists to non-specialist physicians (World Health Organization 2007).

Task shifting has been employed in prevention and management of cardiovascular disease (Ogedegbe et al. 2014) and to improve maternal and child health outcomes, with CHWs tasked to provide health education to pregnant women and new mothers, identify high-risk pregnancies for referral to medical centres, conduct newborn checks, treat newborn infections and refer for further care where necessary, and monitor growth and vaccinations among others (Balsari et al. 2017). In global surgery, obstetrics, and anaesthetics, associate clinicians are increasingly tasked with operations and anaesthesia in place of doctors (Federspiel et al. 2018).

While multiple trials have demonstrated the success of task shifting in expanding access to care without sacrificing the quality of care, there is less evidence to show which factors are critical to maintaining quality of care when such interventions are scaled-up. However, supervision, clear guidelines, adequate initial training, and regular retraining all appear important elements of successful programmes (Mason et al. 2006; World Health Organization 2008).

Digital health technologies

Digital technologies are increasingly included in studies that: address coverage gaps, increase communication with patients, improve diagnosis and treatment, improve data management, and assist in financial transactions (and limit fraud and abuse) within the healthcare system. Technologies include mHealth (mobile health) and computer-based information applications. With rapidly rising access to mobile phones and the internet, delivering health interventions using mobile technologies is increasingly feasible (Lewis et al. 2012).

There is now evidence to demonstrate the value of mHealth interventions across LMICs. SMS reminders have been shown to improve treatment adherence and care seeking as seen with regards to ARVs and malaria diagnostics (Liu and Modrek 2016; Amankwaa et al. 2018); and educational interventions such as MomConnect have been effective at delivering targeted health promotion messages to pregnant women (Seebregtsi et al. 2016). Technology has also enabled task shifting with mobile or tablet-based applications designed to assist health workers in diagnosis and treatment in the field or in primary care (Lewis et al. 2012). Virtual consultations reduce the need for in-person visits to clinics and so increase access to care where geography, transport and financial barriers might exist (Lewis et al. 2012). Furthermore, virtual consultations may be preferred by patients who experience stigma and resist accessing care for fear of being ostracized. In contrast, the use of information system interventions, including electronic health records and data management systems is less well established in MICs.

Despite successful pilot studies, few programmes have been scaled successfully (exceptions including MomConnect in South Africa (Seebregtsi et al. 2016) and the mDiabetes project in Senegal (World Health Organization 2017)). Scaling digital interventions often requires additional investment; electricity and internet access are inconsistent and mobile data is expensive; and there remain cultural and generational barriers to widespread adoption of technological interventions (Lewis et al. 2012; Labrique et al. 2018). Furthermore, despite the imperative for data that underpin learning health systems, many MICs are not making use of available technologies to assist in data collection and management (Lewis et al. 2012).

Intersectoral collaboration

The impact of social and economic transitions on disease burdens and outcomes highlights the multidimensional nature of health and points to the value of intersectoral collaboration in tackling major public health challenges. We have noted the importance of functioning CRVS systems and regular health outcome reporting which often falls outside the remit of health departments; improvements in housing, water, and sanitation are critical to reducing the burden of communicable disease. Intersectoral collaboration is required to tackle persistent inequality in many MICs: targeted social welfare policies seek to support the large ‘tail’ of the population still to emerge from poverty. These tend to be high health burden populations, and policies which redistribute wealth across socioeconomic quintiles assist in lessening the burden on the next generation. The South African non-contributory old-age pension and child support grants are exemplars of pro-poor policies where positive externalities have included health gains beyond the direct grant recipient (Aguero et al. 2006; Case and Menendez 2007).

Conditional cash transfers have been used to address the burdens of poverty and incentivize health behaviours in high-risk populations: in Indonesia, conditional cash transfers improved vaccination rates by up to 30% (Kusuma et al. 2017). while the Oportunidades CCT programme in Mexico and the Bolsa Família programme in Brazil have been associated with improved child health, growth, and development, and increased care seeking among other positive health and education outcomes (Fernald et al. 2008; Shei et al. 2014).

Finally, national taxation policies and regulation of nutrient content in foods are powerful tools for addressing public health burdens. Excise taxes on tobacco, alcohol, and sugar-sweetened beverages are effective strategies to reduce consumption with an ensuing decline in risk, morbidity, and mortality from related diseases (including cardiovascular disease, cancers, interpersonal violence) (Task Force on Fiscal Policy for Health 2019). Mandated salt targets in processed foods are expected to further reduce death rates from heart disease (Webster et al. 2017). Such policies demonstrate the value in governments becoming more adept at nudging their populations to make healthy choices, and suggest that similar approaches can be applied to other products. See Box 1.4.4 for a discussion of tobacco.

Box 1.4.4 The power of tobacco, alcohol, and sugar-sweetened beverage excise taxes

Excise taxes on tobacco have been used effectively in MICs including Brazil, South Africa, Ukraine, Turkey, and the Philippines (Task Force on Fiscal Policy for Health 2019), though there remains room for further increases to meet the WHO recommendation of a 70% excise tax on tobacco (World Health Organization 2010). Figure 1.4.6 shows changes in per capita cigarette sales as prices rose in Brazil: over 2006–2011, the real price of cigarettes rose by 34% per pack, with a corresponding fall of 19% in per capita cigarette consumption. In 2012–2016, the real price of cigarette packs rose by a further 33%, corresponding to an overall decline of almost 50% in cigarette consumption per adult (Task Force on Fiscal Policy for Health 2019).

Russia continues to have one of the highest alcohol consumption rates in the world. However in 2004, laws banning alcohol advertising, restricting availability, and taxing alcoholic beverages were introduced and resulted in a decline in alcohol consumption by a third by 2014 (Task Force on Fiscal Policy for Health 2019). In Mexico the introduction of a 10% sugar-sweetened beverage tax is credited with reducing consumption of sugary drinks by 7.6% over the first 2 years of the tax, with the largest reductions noted among the poorest socioeconomic groups (Colchero et al. 2017). Further projections suggest the tax will prevent 189,300 incident cases of type 2 diabetes, 20,400 strokes and heart attacks and 18,900 deaths in adults 35 years and older between 2016 and 2026 (Sánchez-Romero et al. 2016). A similar policy (Health Promotion Levy) was introduced in South Africa in 2018 and is projected to prevent 8,000 diabetes-related premature deaths over the coming 20 years (Saxena et al. 2019).

Discussion

MICs are diverse in geography, politics, and population size—but all are undergoing social, economic and health transitions which necessitate adaptations of their health system to meet changing needs across the life course. Investing in resilient and learning health systems based on the principle of UHC should enable MICs to deliver care in a context of heterogeneity of outcomes related to persistent inequality in MICs, a triple (or quadruple) disease burden, growing prevalence of multimorbidity, mental and substance use disorders, and the health impacts arising from migration, climate change, and antimicrobial resistance. There is every likelihood that failure to adapt current health system functioning will lead to a divergence between health spending and outcomes—with increased spending failing to generate increased impact. Moreover, the nature of health profiles and burdens evolving in transitioning countries also requires interventions beyond the health sector, highlighting the value of collaboration across sectors and reinforcing a 'health in all policies' approach.

While much of the chapter is focused on the health transitions that accompany economic growth, there are of course economic effects from changing health status: with improved health comes greater productivity and reduced treatment costs (and conversely poor health negatively impacts economic growth). Investment in effective preventive and promotive strategies can be extremely cost-effective across the life course and translate with time into enhanced education and livelihoods. However there is a tension between prioritizing spending on prevention of future disease in the face of prevalent burdens requiring immediate attention. Furthermore, many preventive strategies require investment beyond the health sector—to alter more upstream social, structural, and environmental determinants of health. UHC and intersectoral collaboration are key to managing these competing priorities in order to meet the health needs of transitioning populations given the resources available.

Achieving the necessary health system reforms across MICs will require sustained investment in research and cognisance of the complexity of cultural and contextual 'fit'. We have highlighted a number of areas where further research is needed: accurate data on risk, morbidity, and mortality patterns is critical to designing and monitoring interventions. Better understanding of multimorbidity is urgent, with particular focus on adolescent and young adult populations, both poorly served by existing health infrastructure. The full impact of migration, climate change, and antimicrobial resistance on primary healthcare and agriculture are research agendas which warrant ongoing attention. Research is also necessary to evaluate interventions and generate the data to drive learning health systems—including questions of cultural acceptability and contextual fit which will influence the effects of interventions, and strategies to scale-up. Implementation scientists can advise on integrating routine data into evaluation of health systems performance, and how to effectively convert evidence into practice and policy.

Costs are a challenge facing all countries and a particular challenge for MICs. Health costs will grow as life expectancy increases and disease burdens evolve, and intervention strategies will likely differ for communicable, non-communicable and injury-related burdens—with the implication that parallel investments are required. The suggestion that MICs strive to achieve UHC places further demands on national health services—and an imperative to set priorities. The reality, however, is that MICs will be unable to cover all interventions for all conditions for all people. This is true of even the largest economies (such as China, India, and Brazil) which remain vulnerable to the pressures inherent in the global financial system including trade wars, depressions, and recessions. Many MICs require external support and investment—from bilateral donor countries, philanthropies, and the International Monetary Fund (IMF), World Bank, and UN system—to meet immediate costs and support investment in systems strengthening and health promotion which yield health benefits in the future.

The leadership demands posed by the health challenges facing MICs in transition are substantial with few tried and tested leadership strategies that guarantee improved health outcomes. The challenges highlighted in this chapter impose leadership requirements across all levels of the health sector and spill over into other sectors (including infrastructure, water, social development, housing, education, environmental policy, city planning, legislation, and policing). Successful leaders will be able to influence the political agenda towards achieving UHC, while balancing the challenges of competing interests, and using evidence to buttress policy decisions.

Good policy, though necessary, is not sufficient. Governance—being the capability to strategically implement policy, achieve buy-in, monitor compliance, and hold parties to account—is critical. Although many MICs need to build institutions and strengthen their capacity to monitor public health legislation, successes such as the enforcement of tobacco legislation in Brazil and South Africa can serve as motivation to further develop governance structures.

Conclusion

MICs are countries undergoing complex, often rapid economic and social transitions. Such transitions are typically prolonged and non-linear and pose major challenges to the conventional organization of health systems. Innovative

policies should focus on building resilient and learning health systems better able to deliver UHC, capitalize on intersectoral collaboration, and make use of task shifting and digital health technologies to deliver high-quality care. Investment in further research—to generate new data and better translate evidence into policy and programmes—and enhanced leadership and governance will support MICs in meeting their populations' changing health and development needs.

1.5

Globalization

Kelley Lee

Introduction

‘Globalization’ is a term associated with varied changes to our world, and the net balance of the costs and benefits of these changes to specific individuals and populations remains fiercely debated. There is now substantial scholarship on the links between globalization and public health, explaining how increasing flows of people, other life forms, economic activity, and information worldwide are influencing health determinants and outcomes (Lee 2003b; Labonte et al. 2012; Hanefeld 2015). The greater scale and geographical reach of these flows pose three core challenges for the public health community: how can the evidence base concerning the causal relationship between globalization and health continue to be strengthened; what effective policy responses are needed to optimize globalization’s benefits, and minimize its costs, to population health; and how can these policy options be practically and effectively implemented?

This chapter begins by defining the concept of globalization, and the nature of the changes taking place in the contemporary world as a result. The most prominent feature of globalization—the emergence of a global economy—is then described. The chapter then focuses on how selected public health functions might take account of the changes posed by globalization. Many of the challenges raised in this chapter are addressed in more detail elsewhere in this textbook, reflecting how globalization has come to influence the full spectrum of public health functions. The chapter concludes by considering the prospects for global health governance as the means for strengthening collective action to protect and promote population health. While the public health community is often on the frontline of responding to health risks arising from globalization, it has played only a

limited role to date managing and shaping globalization processes and outcomes. The chapter concludes that addressing the public health impacts of globalization through effective collective action remains essential to the future sustainability of globalization.

What is globalization?

The widespread use of the term ‘globalization’ has been accompanied by variation in its definition. In many cases, the term ‘global’ is used interchangeably with ‘international’ (subjects that concern two or more countries). At other times, globalization is used to refer to specific phenomena such as the spread of fast food restaurants beyond western societies, the worldwide popularity of Hollywood films, or the vast quantities of information digitally available through the internet. Alongside definitional vagueness lie marked differences in how globalization is normatively assessed. Some observers believe globalization as highly desirable for generating economic growth and prosperity for millions (Feachem 2001; Bhalla 2018). Others argue that globalization is a contemporary form of colonialism creating new patterns of inequality within and across countries (Cornea 2001; Labonte et al. 2011). There are contrasting values and assumptions underpinning these starkly different perspectives, resulting in highly contested debates within the research, policy, and advocacy communities.

While it is beyond the scope of this chapter to review the nuances of these debates in detail, an important starting point is to approach the term with a critical lens. In the broadest sense, globalization has become widely understood as the closer integration or interconnectedness of human societies across geographical or territorially-defined boundaries. While this has arguably been occurring over millennia, what is distinct since the late twentieth century has been the vast increases in the types, scale and speed of transboundary flows, and the reach of their consequences. Held et al. (1999) write that it is this greater intensity and extensity of interconnectedness of human societies that distinguish contemporary globalization.

More specifically, the flows associated with globalization can be understood as leading to three types of changes to human connectedness (Lee 2003a). *Spatial change* refers to how people organize and interact across physical or territorial space. The concept of a ‘global village’ derives

from the increased capacity for people to conduct social relations across vast distances because of the greater availability and affordability, for example, of information technologies and long-haul flights. Similarly, the reorganization of the world economy by globalization has enabled ready consumer access to many goods and services produced in faraway locations. This 'death of distance' (Cairncross 2001) includes the formation of new human geographies, such as virtual communities in social media, by which individuals come together across territorial space to interact, exchange, and form identities. In short, the spatial changes resulting from globalization are profoundly shifting how people define, occupy, and navigate geography.

A second, and closely related consequence of globalization, is *temporal change* which concerns how we think about and experience time. The modern world is characterized by an acceleration of the timeframe in which many phenomena occur. For instance, global financial transactions such as foreign exchange, buying and selling equities (stocks and shares), and securing credit can take place in a matter of seconds. New modes of transportation have enabled larger numbers of people to travel greater distances in shorter amounts of time. Mechanization and digitalization have sped up processes of resource extraction, manufacturing, and distribution. The capacity for certain tasks to be done faster, in turn, has driven accelerated change in some parts of society such as business, communications and transportation (Friedman 2012).

Third, globalization is leading to *cognitive change*—how we think about ourselves and the world around us. The production, dissemination, and adoption of new knowledge, ideas, values, and beliefs has become global as a consequence of mass and social media (including the advertising industry), research, and educational institutions, thinktanks, consultancy firms, religious organizations, and political parties. The ascendance of English, as the preferred language for diplomacy, business, and science, is also a reflection of cognitive globalization. Huntingdon (2011) cast such changes within a terrain of epic conflict, a historic 'clash of civilizations' between western and other world views. In contrast, many raise concerns that globalization is leading to western-dominated cultural homogenization, threatening diversity by eradicating local cultures, languages, and belief systems. Others argue that globalization is enabling cultural links across diverse societies to be negotiated, focused on shared ideas and values such as human rights, gender equity, and environmental and labour standards.

Still others see new cultures emerging, a global mélange from processes of hybridization and fusion (Pieterse 2012). Together, spatial, temporal, and cognitive are closely intertwined, creating complex and dynamic impacts on societies worldwide, with both positive and negative consequences.

As well as the nature of the changes caused by globalization, the drivers of globalization have also elicited substantial debate. Mass access to certain technologies, led by information and communication technologies, and transportation, are clear enablers of transboundary flows (Rossignoli et al. 2017). For example, declines in transport costs per ton by sea, due to larger ships, more efficient container management, and consolidation of the industry has been central to the large-scale shift in manufacturing (off-shoring) to lower-cost countries (Wright 2017). Similarly, between 1997 and 2015, the Consumer Price Index for personal computers and peripheral equipment declined by 96% (US Department of Labor 2015).

For some writers, however, technology is the enabler, but not driver, of globalization. They argue that the underlying factors driving such technological changes are economic in nature. The global spread of capitalism has been spurred, on the one hand, by producers seeking cheaper inputs (i.e. raw materials, labour, research and development, transport, and communications), more efficient (and greatest) economies of scale, and ultimately profitable markets. Billions of consumers around the world, on the other hand, fuel this process by demanding higher quality, quantity, and range of goods and services at lower prices. The resulting economic transactions, guided by what eighteenth-century economist Adam Smith called the ‘invisible hand’ of the market, are described as the real force behind globalization (Schuh 2007; Dicken 2015). Globalization, in this sense, is seen as a largely economic and market-driven process of change.

A further perspective rejects globalization as essentially technology or economics-driven process which implies a degree of rationality and progress. Instead, current forms of globalization are arguably driven by particular ideologically-based values and beliefs broadly referred to as neoliberalism. The global spread and dominance of this ideology from the 1980s, and its embedding within global institutional arrangements has, for instance, defined the industrial policies facilitating the development of such technologies (e.g. the promotion of an information economy through deregulation and privatization of the telecommunications sector), and their dissemination for particular purposes (e.g. deregulation of financial

markets). Neoliberalism has also defined economic policies which encourage trade liberalization, market-based competition, and foreign direct investment (e.g. tax incentives), while advocating a minimal role for the state at the expense of social welfare and environmental protections (Slobodian 2018).

Differing perspectives about the drivers of globalization, in turn, underpin varying beliefs about whether, on balance, global changes are leading to net costs or benefits to people and societies. 'Globalists' (supporters of contemporary globalization) anticipate positive benefits overall—a world of shared identities, greater efficiency and productivity, economic growth, and rising prosperity. While a period of transition is recognized, during which accrued benefits may be unevenly distributed, including temporary inequalities in wealth within and across countries, globalists believe that the globalization process is progressive in the longer term, bringing the greatest benefits to the greatest numbers of people. In sharp contrast, opponents hold that there are fundamental flaws underpinning the market-driven logic of contemporary globalization. This logic is producing stark inequalities in wealth and power which are neither temporary nor just. The result is a world increasingly structurally skewed in favour of a relative minority (e.g. those with access to technology, education, capital, and gainful employment) at the expense of a majority disproportionately bearing the costs of globalization (e.g. those with insecure or unsafe employment, low wages, low education). Thus, while globalization may be generating large-scale wealth, critics challenge the assumption that this new wealth will eventually 'trickle down' the global pecking order. Without a strong commitment to redistributive policies, and meaningful social and environmental protections, neo-liberal globalization is seen as widening the gap between the 'haves' and 'have nots' (Mittelman 2002). The greater concentration of the world's wealth in ever fewer hands—the richest 1% increased their share of the world's wealth between 2008 and 2016 from 42.5% to 50.1% (Credit Suisse Research Institute 2017)—is seen as evidence of the structural inequities created by contemporary globalization.

From a public health perspective, there is substantial evidence that globalization is creating diverse and complex changes to health determinants, resulting in both positive and negative health outcomes for specific individuals and populations. Policies to minimize the costs to and maximize the benefits for health, as well as measures to ensure that these

costs and benefits to public health are equitably distributed within and across societies, are arguably central to the longer-term sustainability of globalization (Bacchetta and Jansen 2011). Towards the development of effective policy measures, a fuller understanding of the public health impacts of globalization is required.

The public health implications of a global economy

Economic globalization is characterized by the steady restructuring of production, distribution, and consumption into systems organized on a worldwide scale. While economists disagree about the precise timing of this restructuring, most agree that this has led to a fundamental transformation of the world economy by the latter part of the twentieth century. Key features of this 'global shift' have been the liberalization of capital flows; rise of transnational corporations in major industrial sectors; and the emergence and spread of global production networks. Each of these has implications for public health determinants and outcomes.

The first major pillar of the globalized world economy, the liberalization of capital flows, was introduced in the United States from the mid-1970s. Historically, banks, insurance companies, investment companies, and brokerage firms have been subject to heavy regulation. Deregulation of financial markets, such as the removal of restrictions on the types of securities that financial institutions could trade, levels of interest that could be paid on specific types of securities and bank accounts, and types of institution entitled to act as financial intermediaries, was introduced to increase competition and encourage capital flows within and across countries. Information and communication technologies enabled high-speed electronic-based transactions which eventually linked financial markets across countries. The result has been a globally integrated financial market capable of 24-hour trading in foreign exchange, commodities, capital, and other financial assets (Valdez 2006). The world's financial assets have correspondingly boomed, from US $136 trillion in 2005 to US $294 trillion in 2014 (Witkowski 2015). By 2020, this is expected to rise to US $371 trillion, with one-third accounted for by emerging economies (Roxburgh et al. 2011).

A second key pillar is the increased international trade of goods and services. While trade has been the lifeblood of commerce for thousands of

years, it is the global restructuring and integration of production, accompanied by the increased scale and scope of trade, which characterizes the world economy since the late twentieth century. Historically, trade among countries has been dominated by raw materials and natural resources (e.g. oil, timber), commodities (e.g. grains, metals), or manufactured products (e.g. textiles and clothing, food products). In 1948, the General Agreement on Tariffs and Trade (GATT) was established as an agreement under which signatories could negotiate reductions in tariffs on traded goods. Eight trade rounds were carried out between 1948 and 1994 by which thousands of tariff reductions were negotiated. During this period, membership grew from 23 countries in 1947 to 125 countries in 1994, thus establishing a worldwide trading system.

The growth of international trade led to renewed support for a permanent organization, resulting in the creation of the World Trade Organization (WTO) in 1995. As of 2018 there are 164 member states and 23 observer states, many of which are seeking accession. Moreover, the WTO's remit embraces trade in services, agriculture, intellectual property rights, government procurement, and other areas (Wilkinson 2014). The overall effect has been that world trade grew faster than world output. Between 2006 and 2016, for example, world merchandise exports increased from US $8 to US $11 trillion (37.5%), and commercial services exports from US $2.9 to US $4.8 trillion (66%) (WTO 2017a), between 1.1 and 2 times faster than global gross domestic production (GDP). The global financial crisis beginning in 2008 led to a significant downturn in trade volumes, with trade eventually growing slower than global GDP in 2016. Nevertheless, since 2017 the overall trend in world trade has once again been growth (WTO 2017b; WTO 2018).

The global restructuring of production and exchange processes has been an integral part of this boom in international trade. In many sectors, transnational corporations (TNCs) have emerged which have relocated components of their business to different parts of the world. Thus, resource extraction may take place in one country, manufacturing in another, and research and marketing in still others (Dicken 2015). The targeted consumers have also changed, with TNCs seeking markets worldwide for global brands. According to the European Brand Institute (2017), the ten most valuable global brands are Apple, Google, Microsoft, Coca Cola, AT&T, Amazon, Johnson & Johnson, China Mobile, Verizon, and Facebook.

Global economic restructuring can be observed in many industrial sectors posing distal or proximal impacts on health determinants and outcomes. One important example is the pharmaceutical industry which has become dominated globally by large companies formed through mergers and acquisitions. This includes the buying of domestic generic and manufacturing companies to access emerging markets, and the consolidation of the pharmaceutical and biotechnology industries. Table 1.5.1 describes the largest pharmaceutical companies in 2016 by revenue. In 1992, the ten largest companies accounted for one-third of global revenue (Tarabusi and Vickery 1998). By 2016, this had increased to 40%. This consolidation of the market has been driven by intense competition, the high cost of research and development (R&D), economies of large-scale manufacturing, and the need for capacity to market and distribute worldwide (Wright 2017). For example, the reported cost of developing and bringing a new prescription drug to the market is now around US $2.6 billion, a 145% increase since 2003 (Mullin 2014). Success in the pharmaceutical sector amid globalization requires large companies with global reach and access to considerable resources.

Table 1.5.1 World's ten largest pharmaceutical companies (2016)

Company	HQ	Revenue (millions US$)	Growth over previous year (%)
Pfizer	United States	52,824	+8
Novartis	Switzerland	48,518	-2
Merck	United States	39,807	+1
Roche	Switzerland	38,369	+5
GlaxoSmithKline	United Kingdom	37,929	+7
Sanofi	France	35,633	-1
Johnson & Johnson	United States	33,464	+7
Gilead	United States	30,390	-7
Abbvie	United States	25,638	+12
AstroZeneca	United Kingdom	23,002	-7

The alcoholic beverages industry, worth an estimated US $645 billion in 2017 and projected to reach US $1,594 billion by 2022 (Allied Market Research 2017), is another health-related example of the global restructuring of the world economy. As market saturation and increased regulation may moderate growth in North America, Europe, and Australia/New Zealand, the industry has turned to emerging markets notably in Asia (Esser and Jernigan 2018). The ability to compete globally, in turn, is prompting mergers and acquisitions, and the increasing domination in parts of the industry by transnational alcohol companies (TACs). For example, beer manufacturing is led by Anheuser-Busch InBev, Heineken and Carlsberg which produced 38% of global supply in 2016. The spirits and wine sectors are less concentrated to date, but further globalization of production, distribution, and consumption is expected to be spurred by intensifying competition for

new markets, new product development and marketing, and trade and investment liberalization (Mitchell and Casben 2016).

The direct public health consequences of economic globalization arise from changes in the production, distribution, and consumption of either health promoting or health harming products and services. Where a product is inherently health harming, such as tobacco, an increase in risk is posed to public health. This is not withstanding the use of non-combustible nicotine products such as electronic cigarettes, increasingly produced and marketed by the tobacco industry itself, to potentially mitigate although not remove such risks if used exclusively instead (National Academies of Sciences, Engineering and Medicine 2018). For other potential health harming products, such as alcoholic beverages, food and drink, the level of risk depends on the specific product or amount consumed. Globalization, in this case, may create a mixture of benefits and harms. For example, many products of the pharmaceutical industry are essential to healthcare worldwide. The increased production and affordability of such products, through improved economies of scale to serve larger markets, increased spending on R&D, and innovations in distribution would accrue benefits to health. However, the competitive pressures caused by economic globalization can also lead 'Big Pharma' to unduly focus on the most profitable products and markets to recover investment or maximize returns for shareholders. This can skew production decisions away from diseases and populations deemed to offer insufficient financial returns (Trouiller et al. 2002), and allow companies to price their products beyond the affordability of many who need them. This lack of access to patent-protected medicines has led to ongoing tensions worldwide between ensuring an economic return for Big Pharma and enabling equitable access to improve health outcomes. The Treatment Action Campaign initiated in South Africa in 1998 by HIV/AIDS activists, which has pressed the government to make various drug treatments more readily available in the country (Heywood 2009), and the licensing of generic drug production by the Thai government despite industry pressure to enforce patent protections under the TRIPS agreement (Yamabhai et al. 2011), illustrate this tension between private and public interests.

More indirectly, the global economy can adversely impact human health by enabling conditions that pose new risks. These risks can arise in several ways. First, economic globalization has encouraged unprecedented

population mobility. Population movements are not new—humankind has been on the move since *Homo erectus* migrated out of Africa in about 1 million BC. What characterizes population mobility since the late twentieth century has been its volume, geographical reach, speed, and frequency. Globalization is what Castles and Miller (2009) call the 'age of migration'. In 2017, the number of international migrants reached 258 million people, an increase from 173 million in 2000. By 2017, 244 million people lived outside their country of birth, compared with 156 million in 1990 (UNDESA 2017). The reasons why people migrate are diverse. For the relatively educated, highly skilled, and mobile, economic globalization offers new training and employment opportunities. For the lower educated and skilled, work opportunities in places of 'global employment' may beckon, such as the offshore factories of TNCs, fields of cash crops grown by the agri-food industry, or the extraction sites of the natural resources industries. Changing patterns of population mobility and settlement may contribute benefits to health through, for example, providing new training opportunities to health workers or enabling vulnerable populations to move from locations posing risks. Increased population mobility may also generate new risks by, for example, heightening the risk of communicable disease outbreaks where refugee settlements do not have adequate housing, water, and sanitation; facilitating the spread of communicable disease outbreaks globally via long distance travellers; or weakening healthcare systems in low and middle-income countries (LMICs) through the depletion of domestic healthcare workers.

Second, economic globalization can increase environmental health concerns, ranging from local, small-scale factors (e.g. household exposures) to widespread exposures affecting whole populations. The possible impacts of globalization on environmental health are wide-ranging, potentially affecting populations at the global, regional, community, occupational, and household levels. These impacts can be direct, such as through the dumping of hazardous waste across borders, relocation of risky occupations (such as ship breaking or asbestos disposal), and damage caused by cross-border pollution or contamination. Economic globalization, in which companies compete on a worldwide scale to increase returns, is raising concerns that profit-maximization motives can undermine environmental health. Governments, seeking to attract foreign direct investment or unleash market competition to fuel economic growth and generate employment, are accused

of engaging in a 'race to the bottom' by offering reduced tax rates, lower wages, or weaker environmental, labour, and health and safety protections (Mosley and Uno 2007). A change in investment or lending policy at the global level can also have health consequences for local communities. For example, policy conditions set by the World Bank, or requirements to repay substantial sums of foreign debt, can restrict the public expenditure of borrowing countries on environmental protection or investment in basic infrastructure, such as water and sanitation. A cholera outbreak in South Africa in 2000–2001, which led to around 120,000 cases and 265 deaths, has been blamed on the introduction of user fees following the privatization of water utilities as part of the country's structural adjustment programme. As water supplies were cut to poor people unable to pay for the new charges, many resorted to using polluted river water (Anonymous 2006). The World Bank (2000) argues that '[e]very society has to decide for itself on the relative value it places on economic output and the environment'. Others argue, however, that there are substantial inequities in terms of who bears the environmental costs of globalization (Wiedmann and Lenzen 2018).

Third, the rapid growth, open nature, and regulatory challenges of the global economy have led to a substantial growth in illegal products, many of which pose risks to human health. The illicit tobacco trade, for instance, is believed to account for 9 per cent of retail sales, increasing access to lower-priced and unregulated cigarettes (WHO n.d.). Around 5 per cent of the global population aged 15–64 have used illicit drugs at least once in 2015. The production, distribution, and consumption of such drugs, since the late twentieth century, have been transformed by transnational networks of criminal organizations (UN Office on Drugs and Crime 2017). A related problem is the global business of counterfeiting which was worth US $1.2 trillion in 2017 (Research and Markets 2018). Many counterfeits are health-related or affecting products, notably pharmaceuticals, and food and beverage products. WHO estimates that one in ten medical products circulating in low- and middle-income countries is either substandard or falsified (WHO 2017a). Counterfeit baby milk powder containing melamine reportedly caused 50 child deaths and acute malnutrition in more than one hundred others in rural China (Watts 2004). Deaths from counterfeit alcohol products have led to hundreds of deaths in countries worldwide including Indonesia (Faridz and Griffiths 2018), Russia (Reevell 2016), Ireland (McNamee 2016), and Mexico (ACS Sensors 2018). Economic globalization

has flourished through the creation of special economic zones, global financial systems, worldwide transportation networks, and internet sales. The same systems have been harnessed by criminal organizations to produce and distribute illicit goods with health harming effects. As discussed next, in relation to global health governance, within efforts to strengthen the regulatory frameworks managing globalization, there is much need for increased measures to protect and promote population health.

Globalization and essential public health functions

Public health is concerned with protecting and promoting the health of whole populations within and across countries. Since the late twentieth century, there have been efforts in many countries to reinvigorate public health systems. The Institute of Medicine, for example, initiated debate in the United States through its reports, *The Future of Public Health* (Institute of Medicine 1988), and *The Future of the Public's Health in the 21st Century* (Institute of Medicine 2002), with the latter identifying the need to address 'emerging threats' caused by rapid changes to the nation's social, cultural, and global contexts, scientific and technological advances, and demographic shifts (Institute of Medicine 2002). Given an inadequate capacity to response to the SARS (severe, acute respiratory syndrome) in 2003–2004, the Canadian government formed the Public Health Agency of Canada (PHAC). Correspondingly, the creation of the European Centre for Disease Control (ECDC) in 2004 was to strengthen the capacity of European Union countries to respond to infectious disease outbreaks. Over the past decade, there has also been similar investments to build public health systems in such countries as India (Planning Commission of India 2011), Brazil (Jerberg 2008), and China (Liang and Burns 2017).

While disease outbreaks prompted renewed attention to public health systems in many countries, WHO and national policy makers now recognize the need to adapt a fuller range of essential public health functions (EPHFs) to meet the challenges of a globalizing world (Martin-Moreno et al. 2016). As described earlier, spatial, temporal, and cognitive changes arising from globalization are having important impacts on a broad range of population health determinants and outcomes. The remainder of this chapter describes how globalization has implications for three EPHFs identified by the Pan American Health Organization (PAHO 2002)—monitoring, evaluation, and

analysis of health status; public health surveillance; and health promotion—and how the public health community might effectively adapt to these impacts (see Box 1.5.1).

Box 1.5.1 Essential public health functions

EPHF 1 Monitoring, Evaluation, and Analysis of Health Status
EPHF 2 Public Health Surveillance, Research, and Control of Risks and Threats to Public Health
EPHF 3 Health Promotion
EPHF 4 Social Participation in Health
EPHF 5 Development of Policies and Institutional Capacity for Planning and Management in Public Health
EPHF 6 Strengthening of Institutional Capacity for Regulation and Enforcement in Public Health
EPHF 7 Evaluation and Promotion of Equitable Access to Necessary Health Services
EPHF 8 Human Resources Development and Training in Public Health
EPHF 9 Quality Assurance in Personal and Population-based Health Services
EPHF 10 Research in Public Health
EPHF 11 Reduction of the Impact of Emergencies and Disasters on Health

Monitoring, evaluation, and analysis of health status

Assessing the health of a given population is the starting point for a wide range of public health actions including priority setting, resource allocation, the design and implementation of interventions, and programme evaluation. There are well-recognized steps for assessing population health status:

Define the purpose of the assessment.
Define the population concerned and any comparator population.
Define the aspects of health to be considered.
Identify and review existing data sources.
Select the most appropriate existing data (Gentle 2001).

However, assessing population health status within the context of globalization presents two key challenges. First, there remains variable

capacity within and across countries to collect and manage the essential health information needed. In many LMICs, in particular, inadequate health information systems results in data of variable quality or incomplete regarding selected populations and health conditions. According to WHO (2006a):

> A country health information system comprises the multiple subsystems and data sources that together contribute to generating health information, including vital registration, censuses and surveys, disease surveillance and response, service statistics and health management information, financial data, and resource tracking. The absence of consensus on the relative strengths, usefulness, feasibility, and cost-efficiency of different data collection approaches has resulted in a plethora of separate and often overlapping systems.

To address this problem, the Health Metrics Network (HMN) was formed in 2005 as a global partnership hosted by WHO to advocate for the strengthening of health information systems in LMICs. Funded by the Gates Foundation and other donors, the partnership was comprised of governments, multilateral and bilateral development agencies, foundations, global health initiatives, and technical experts that aimed to increase the availability and use of timely, reliable health information. In 2013, the WHO Executive Board decided to discontinue the HMN because the network was deemed to have ‘fulfilled its time-limited and catalytic role’ of ‘raising the profile of health information systems, helping countries to assess and strengthen their systems and accelerating improvements to country civil registration and vital statistics systems’ (WHO 2013). The focus has turned to harnessing the capacity of global information and communication systems for a wide range of health applications including monitoring, evaluation, and analysis of health status (de Fatima Marin et al. 2017). While improvements in health information systems have been achieved across many LMICs, including the innovative application of mobile technologies, resource constraints continue to pose the largest problem.

A second challenge is the limitations of existing health information systems for capturing health status and needs that do not conform with, or cut across, national boundaries. For each country, health data is collected and managed by local and national health departments and associated institutions. The WHO Statistical Information System (SIS), now part of the Global Health Observatory (GHO), in turn, collates this data to produce aggregated health indicators, mortality and health status, disease statistics, health system statistics, risk factors and health service coverage, and

inequities in health from member states. These data are compiled in the *World Health Statistics*. Governments, donors, and other organizations may use these data to identify health priorities.

The impacts of globalization on health, however, are by definition transcendent of national borders such that new health and disease patterns may be emerging that may not be captured by aggregated or disaggregated national data. A good example is the complex pattern of rising overweight and obesity rates. In high-income countries, obesity is rising rapidly across all socioeconomic groups but is particularly associated with social deprivation. In the United States, for example:

> CSD [community socioeconomic deprivation] was associated with higher BMI [body mass index] at average age [of study cohort] (10.7 years) and with more rapid growth of BMI over time. Children born in communities with greater CSD had steeper increases of BMI at younger ages. Those born into the poorest communities displayed sustained accelerated BMI growth. CSD remained associated with BMI trajectories after adjustment for a measure of household socioeconomic deprivation. (Nau et al. 2014)

In France, Romon et al. (2005) found that genetic predisposition influences the prevalence of obesity and changes in BMI among children from the higher social class. For children within the lowest social class, which has seen an increase in BMI across the whole population, environmental factors appear to have played a more important role. In LMICs, the total number of obese or overweight people has grown rapidly in such diverse countries as Kenya, China, India, and Brazil, notably among a rising middle class. This includes a 10-fold increase in obese children and adolescents in LMICs (NCD Risk Factor Collaboration 2017). At the same time, many urban populations within the lower social classes are experiencing rising rates of overweight and obesity, now exceeding rates of undernutrition (Ford et al. 2017). Trends in over/undernutrition, in other words, are complex and dynamic, requiring detailed and comparable data across population groups defined along variables such as age, gender, socioeconomic status, geography, and occupation.

The challenges of monitoring, evaluating, and analysing health status, within the context of globalization, can be illustrated by a wide range of other examples. The emergence of a global economy dominated by TNCs, for example, has restructured employment around global value chains as leading modes of production, distribution, and consumption. This has led to the employment of millions of factory workers throughout the world, creating

new sources of employment, but often under conditions of weak social and environmental protections (Phillips 2017). How might we measure the changing health status of these workers over time and place? What public health needs do these workers share across domestic jurisdictions which arise, not from their nationality, but from their conditions of employment? The unprecedented movement of people across national borders also requires appropriate ways to understand the health status and needs of varied types of migrants such as tourists, refugees, overseas workers, and trafficked people. Some patterns of migration will not be captured by aggregated national data, thus obscuring the public health needs arising for home and host populations. Similarly, the public health impacts on population health from climate change need to use measures beyond national data given the planetary scale of the environmental effects taking place. These examples illustrate the need for methods that identify new population groups arising from globalization's impacts which do not conform to national borders, and enhanced health information systems which generate corresponding data to monitor, evaluate, and analyse the health status of these populations.

Public health surveillance, research, and control of risks and threats to public health

The just-described need for genuinely global health data, beyond aggregated national level data, underpins the core public health function of preventing, controlling, and responding to public health risks. Traditionally, this function has focused on disease outbreaks and epidemics. Historically, risks from disease-causing microbes have long mirrored the migration and settlement patterns of human species. The shift from hunting-gathering to agrarian societies and the domestication of animals, between 8000 and 3500 BC, for example, brought new risks from zoonotic diseases (Swabe 1999). The so-called 'Columbian exchange', following the arrival of Christopher Columbus in the Americas, is noted for the widespread exchange of plants, animals, foods, human populations (including settlers and slaves), and ideas that followed. Diseases, such as cholera, influenza, measles, malaria, smallpox, and tuberculosis, were also exchanged, resulting in the decimation of Indigenous peoples (Crosby 1972). The influenza pandemic of 1918–1919, which killed around 25 million people worldwide, was undoubtedly

enabled by the large-scale population movements and devastation caused by the First World War. The changing structures of human societies over time and place, in short, give rise to particular health risks.

In this context, contemporary globalization can be understood as altering the structure of human societies once again in ways that pose new risks to human health. First, globalization may alter the *population size* at risk due to patterns of settlement. The world's urban population will almost double, from 3.3 billion in 2007 to 6.3 billion in 2050, with most of this growth in cities within the developing world. Rapid urbanization has been accompanied, in many cases, by poverty, inadequate housing, limited access to clean water and sanitation, or basic healthcare. This has created larger populations now vulnerable to infectious disease risks (Alirol et al. 2010). One of the factors attributed to the unprecedented magnitude of the Ebola virus outbreak in West Africa during 2014–2015, for instance, is that the continent has had the world's highest urban growth rate for 20 years. Rapid urbanization, prompted in large part by war and poverty, may explain how Ebola shifted from relatively small outbreaks at village level to a much larger outbreak putting millions at risk (Mackenzie et al. 2014).

Moreover, globalization has increased the size of populations at risk due to far greater mobility of human and animal species. Diseases have a greater capacity to spread more rapidly and further afield in a more interconnected world. Some infections, such as tuberculosis and cholera, are historically associated with poverty but may now pose new patterns of risk due to globalization (Gushulak and MacPherson 2004). United Nations peacekeepers from Nepal arriving in earthquake-affected Haiti in 2010 are alleged to have caused a devastating cholera outbreak within an already highly vulnerable population (Gladstone 2017). In other ways, globalization is 'democratizing' disease risks. The spread of SARS in 2002–2003, from China to around 25 countries within weeks, posed a threat to populations rich or poor in a world of migrant workers, business travellers, and long-haul flights. The human health risks potentially arising from highly pathogenic pandemic influenza would be truly global by virtue of the widespread lack of immunity, and rapid person-to-person transmission facilitated by highly mobile human populations. Further concerns relate to the global spread of antimicrobial drug-resistant organisms and drug-resistant infectious diseases by mobile human populations. As MacPherson et al. (2009) write: 'Current population movement dynamics rapidly and effectively link regions of

marked health disparity, and these linkages can be associated with risk for importation of drug-resistant infectious diseases.'

Second, globalization may influence the *prevalence* (number of people with a disease within a given population) and *incidence* (number of new cases of a disease in a specified period of time per total population) of certain diseases. De Vogli and Birbeck (2005) argue that vulnerability to HIV/AIDS, tuberculosis, and malaria is closely linked to poverty, gender inequality, development policy, and health sector reforms that involve user fees and reduced access to care. Dorling et al. (2006) similarly argue that 'global inequality in wealth will have compounded the effects of AIDS on Africa', notably caused by globalization-related policies such as structural adjustment programmes. Changing employment patterns and conditions, arising from economic globalization, have also had epidemiological consequences. Moody (2007) describes the globalization of the mining industry and its impact on local communities. Basu et al. (2009) observe how tuberculosis incidence among southern African miners is ten times greater than the general population, with migration to and from mines amplifying tuberculosis epidemics in the general population.

Third, globalization is increasing the *risks from emerging and re-emerging diseases*. Environmental degradation, such as rainforest destruction and intense farming methods, can bring human and animal populations into closer contact. Sixty per cent (60%) of emerging infectious diseases that affect humans are zoonotic (originating in animals), and more than two-thirds of those originate in wildlife including HIV and AIDS, West Nile, Ebola virus, Lyme disease and possibly SARS-CoV-2. The detection and rapid spread of a novel coronavirus, the Middle East Respiratory Syndrome coronavirus (MERS-CoV), from Saudi Arabia to South Korea in 2012, illustrated what Gannon (2015) calls 'a general archetype for emerging infectious diseases: zoonotic in origin, carried across continents by an infected air traveller, initially undiagnosed, bringing fear and economic disruption, and spreading most quickly through vulnerable populations'. Moreover, evidence by Smith et al. (2014) suggest that 'the total number and diversity of outbreaks, and richness of causal diseases increased significantly' from 1980 to 2013.

This heightening of public health risks within a globalizing world has prompted efforts to improve capacities in surveillance, research, and control measures. Globalization offers opportunities, for instance, to harness

information and communication technologies to enable faster, cheaper, and more efficient gathering and worldwide sharing of knowledge. ProMED-mail (see Box 1.5.2) and regional disease surveillance networks have facilitated the collection and reporting of epidemiological data. The lessons learned from SARS prompted renewed WHO efforts to revise the International Health Regulations (IHR), which came into effect in 2007, including the harnessing of a broader range of information sources. The expanded scope of the IHR beyond a handful of named diseases, to the broader concept of 'public health emergencies of international concern' also reflected recognition of the need for collective action on a more diverse range of global health risks. Global technologies are also enhancing research capacities in data analysis, such as genomics, and the use of so-called 'big data' source including the innovative harnessing of non-health global scale data. For example, the use of airline travel data to model transmission dynamics and potential impact of the West African Ebola virus outbreak provided lessons for enhancing real-time epidemiological assessment in future outbreaks via improved data collection and analyses (Cori et al. 2017). There remain critical challenges to harnessing big data, to improve the capacity of countries to respond to global public health risks, namely better understanding of what big data is most useful, how to accurately interpret such data for public health purposes, and how to protect individual privacy and the proprietary interests of data holders (Lazer and Kennedy 2015).

Box 1.5.2 Programme for Monitoring Emerging Diseases (ProMED-mail)

ProMED—the Program for Monitoring Emerging Diseases—is an internet-based reporting system dedicated to rapid global dissemination of information on outbreaks of infectious diseases and acute exposures to toxins that affect human health, including those in animals and in plants grown for food or animal feed. Electronic communications enable ProMED to provide up-to-date and reliable news about threats to human, animal, and food plant health around the world, 7 days a week. By providing early warning of outbreaks of emerging and re-emerging diseases, public health precautions at all levels can be taken in a timely manner to prevent epidemic transmission and to save lives.

ProMED is open to all sources and free of political constraints. Sources of information include media reports, official reports, online summaries, local observers, and others. Reports are often contributed by ProMED subscribers. A team of expert human, plant, and animal disease moderators screen, review, and investigate reports before posting to the network. Reports are distributed by email

to direct subscribers and posted immediately on the ProMED web site. ProMED currently reaches over 70,000 subscribers in at least 185 countries.

Global health promotion

There is now substantial evidence of a marked rise in the global burden of non-communicable diseases (NCDs) since the 1980s. This includes an almost quadrupling of the total number of adults worldwide with Type 2 diabetes (NCD Risk Factor Collaboration 2016) since 1980, and a tripling of the rate of obesity since 1975 (WHO 2017b). In 2017, NCDs killed 40 million people worldwide and accounted for 70% of all deaths. Cardiovascular diseases accounted for most NCD deaths (17.7 million people annually), followed by cancers (8.8 million), respiratory diseases (3.9 million), and diabetes (1.6 million) (WHO 2017c). WHO predicts that, while infectious diseases like malaria, tuberculosis, and HIV/AIDS will largely decline, cancers and ischaemic heart disease, as well as cerebrovascular disease, will continue to steadily rise from 2015 to 2030 (WHO 2018a).
The clarity of evidence about this rapid rise in NCDs across societies at all levels of development, and within populations spanning varying levels of socioeconomic status, has been attributed in part to changes associated with globalization. As Gostin (2014) writes:

> Rapid travel, mass migration and the globalization of culture are known to fuel the spread of infectious diseases. The same factors are also increasing the incidence of non-communicable diseases (NCDs) such as cancer, diabetes and heart disease. As developing countries prosper, these conditions are a by-product of rising air pollution, physical inactivity, and consumption of alcohol, tobacco and excess calories.

This association, in turn, has prompted greater efforts to strengthen collective action on NCDs including global health promotion. Health promotion is the process of enabling people to increase control over, and to improve, their health (WHO 1986). Interventions address three areas of activity to prevent disease and promote the health of a community: communication, service delivery, and enabling factors (individual and structural) which influence the chance of an intention being carried out and a behaviour sustained. Individual enabling factors include communication

skills and literacy; structural enabling factors include social supports, income level and cultural attitudes (Walley et al. 2001, p. 147). A global approach to health promotion takes account of the ways in which globalization may be influencing the social determinants of health, and in turn health behaviours, as well as, offers opportunities for providing appropriate interventions. The Bangkok Charter for Health Promotion in a Globalized World adopted in 2005 recognized the major challenges posed by globalization, and the actions and commitments needed to address the determinants of health in a globalized world by reaching out to people, groups, and organizations that are critical to the achievement of health. To galvanize concerted action by governments, three UN General Assembly High-Level Meetings have been held on the prevention and control of NCDs. The first adopted a Political Declaration on NCDs (2011), and the second followed with an Outcome Document on NCDs (2014), with the target of reducing premature NCD mortality by 25% by 2025 (WHO 2018b). However, the virtual absence of heads of state at both meetings was a disappointment for the NCD Alliance (largely composed of civil society organizations). A 2017 progress report revealed 'uneven and insufficient' progress in most countries in meeting globally agreed targets including a substantial number of countries without NCD national plans and targets (Ravelo 2017). To address the lack of political will, and propose 'bold and practical actions steps to scale up prevention and treatment of NCDs and provide health for all' (WHO 2018c), WHO appointed an Independent High-Level Commission on Noncommunicable Diseases, co-chaired by the heads of state of Uruguay, Sri Lanka, Finland, Russia, and Pakistan. The challenges faced by the Commission in its deliberations, and for societies worldwide seeking to tackle NCDs, is well-illustrated by two of the leading risk factors—obesity and tobacco use.

The rapid increase in overnutrition and obesity, among adults and children, has attracted substantial public health concern in recent years (Fig. 1.5.1). According to WHO (2017b), around 1.9 billion people worldwide are overweight, of which around 650 million people worldwide are obese (BMI >30). At least 340 million school-age children are overweight or obese. The number of overweight or obese infants and young children (aged 0 to 5 years) increased from 32 million globally in 1990 to 41 million in 2016, and expected to rise to 70 million by 2025 (WHO 2017d). Importantly, while obesity rates are higher in wealthier countries than LMICs, these changes

span populations in diverse settings and income levels, including such wide-ranging countries as India, Nigeria, Mexico, and China. The association to globalization of obesity and overweight populations began to be identified in the 1990s. For example, Drewnoski and Popkin (1997, p. 32) write:

> Whereas high-fat diets and Western eating habits were once restricted to the rich industrialized nations . . . the nutrition transition now occurs in nations with much lower levels of gross national product (GNP) than previously . . . First, fat consumption is less dependent on GNP than ever before. Second, rapid urbanization has a major influence in accelerating the nutrition transition.

Prentice (2006, p. 93) attribute these trends to the globalization of food production and lifestyles:

> The pandemic is transmitted through the vectors of subsidized agriculture and multinational companies providing cheap, highly refined fats, oils, and carbohydrates, labour-saving mechanized devices, affordable motorized transport, and the seductions of sedentary pastimes such as television. This trend has been linked to the globalisation of sedentary lifestyles alongside changes in food production and consumption.

Beyond anecdotal and descriptive evidence, Goryakin et al. (2015) undertook extensive econometric analyses of several datasets, using a series of new proxies for different dimensions (social, political, and economic) of globalization potentially affecting overweight in up to 887,000 women aged 15–49 living in 56 countries between 1991 and 2009. They found that both political and especially social globalization dimensions appear strongly positively related to the greater overweight risk, while the association with economic globalization countries is dependent on ‘country-specific factors such as economic development and infrastructure, education, attractiveness of economies to investors, as well as the size of the market’ Goryakin et al. (2015, p. 74). Overall, this evidence supports the hypothesis that the multitude of yet interrelated changes in diet, levels of physical activity, and the built environment associated with globalization are substantial and significant explanations for the sharp rise in obesity and overweight worldwide since the 1980s.

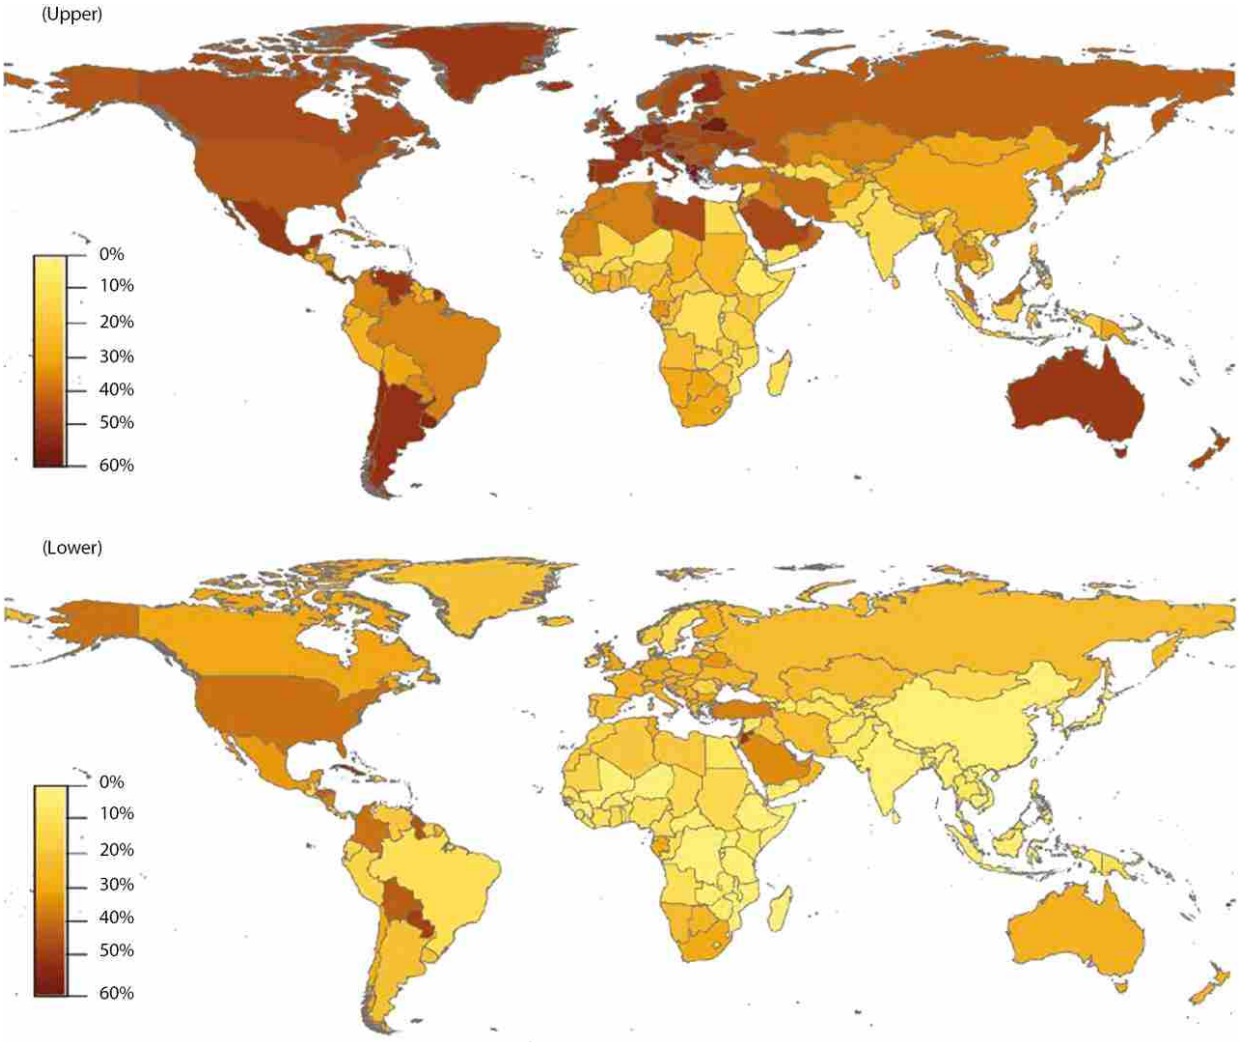

Fig. 1.5.1 Worldwide age-standardized prevalence of overweight (upper) and obesity (lower) in adults 20 years and older by country in 2005.

The few measures adopted to address so-called 'globesity' (Costa-Font and Mas 2016) to date have focused on modifying individual behaviours or lifestyles. These measures emphasize public health education led by healthy eating initiatives and the promotion of increased physical activity. However, more comprehensive approaches to global health promotion are increasingly recognized as necessary. This includes addressing the structural factors that constrain or enable healthy eating, and adopting both supply and demand-side measures concerning what and how food is produced, marketed, and consumed. For example, the Institute of Medicine (2005) report, *Food*

Marketing to Children and Youth: Threat or Opportunity? recognizes that dietary patterns begin in childhood and are shaped by the interplay of genetics and biology, culture, and values, economics, physical and social environments, and commercial media environments. The report includes a comprehensive review of the scientific evidence on the influence of food marketing on diets and diet-related health of children and youth. It concludes that environments supportive of good health require leadership and action from the food, beverage, and restaurant industries; food retailers and trade associations; the entertainment industry and the media; parents and caregivers; schools; and governments. Prior to the Second UN High-level Meeting on NCDs in 2014, WHO Director-General Margaret Chan stated, 'The globalization of unhealthy lifestyles is by no means just a technical issue for public health. It is a political issue. It is a trade issue. And it is an issue for foreign affairs' (WHO 2014). Similarly, following its initial technical consultation in 2018, the WHO Independent High-level Commission on NCDs has argued for a whole-of-society approach (WHO 2018b).

The regulation of the agri-food industry amid globalization, however, remains a major challenge. The concentration of ownership in the food industry, to be dominated by a small number of large transnational food companies, has been achieved by greater economies of scale, lower-cost production methods, and heavy marketing of high-profit foods. This has led to a substantial increase in the production and consumption of highly processed foods which contain industrially-produced ingredients such as high-fructose corn syrup and palm oil. The marked rise in hypertension, heart disease, and type 2 diabetes worldwide, coinciding with the ready availability and affordability of food products produced from such ingredients, continues to be studied (Bray 2013; Ismail et al. 2018). In the meantime, debates about the regulation of such ingredients have intensified. Many public health advocates call for governments to adopt improved and mandatory labelling, and even restrictions on their use. At the global level, WHO called for the adoption of a Global Strategy on Diet, Physical Activity, and Health. However, these efforts were hindered by the agri-food industry's opposition to explicit recommendations on healthy levels of salt, sugar, and fats intake, and subsequently given no regulatory 'teeth' by member states (Lang et al. 2006; Johnson 2012). Instead, the agri-food industry has promoted voluntary self-regulation such as limits on the targeted marketing

of processed food products at children and corporate social responsibility initiatives. The industry has also emphasized the importance of protecting consumer choice, and the primary importance of non-food factors such as physical activity as a health concern. However, Lang et al. (2006) assessed compliance by 25 of the world's largest food manufacturers and retailers to recommendations concerning ingredients, advertising, portion size, and labelling. Only a small proportion of companies voluntarily reduced salt, sugar, and fats in their products. In Spain, León-Flández et al. (2017) found a decline in compliance with the Spanish code of food and drinks advertising directed at children under 12 since 2008. In the US, as Kelly (2005) advises:

> So far the U.S. government has declined to regulate the aggressive ways in which food producers market high-energy, low-nutrition foods to young people. That public-health responsibility has been left to an industry-created scheme of self-regulation that is deeply flawed; there is a compelling need for government involvement.

Similar lessons for global health promotion can be drawn from tobacco control.

Like the agri-food industry, the tobacco industry has globally restructured and is now dominated by a small number of large TNCs. Industry consolidation has been achieved, for example, by the establishment of global value chains, development of 'global drive brands', and intense marketing in emerging markets (Lee et al. 2016). As WHO Director-General Gro Harlem Brundtland (2000, p. 2) stated, in initiating the Framework Convention on Tobacco Control (FCTC) negotiation process in the 1990s:

> [O]ver the past fifteen years, we have seen that modern technology, has limited the effectiveness of national action. Tobacco advertising is beamed into every country via satellite and cable. Developing countries are the subject of massive marketing campaigns by international tobacco companies. In the slipstream of increasing global trade, new markets are opened to international tobacco companies which see these emerging markets as their main opportunity to compensate for stagnant or dwindling markets in many industrialized countries.

The negotiations faced intense efforts by the tobacco industry to limit stronger regulation by participating in some national delegations, lobbying leaf-producing countries and farmers, orchestrating criticism of WHO, and even challenging the science on tobacco and health (Wipfli 2015). Despite industry opposition, the FCTC was signed in 2003 and came into effect in 2005. As of 2018, 181 countries are parties to the treaty. Importantly, the FCTC remains the most prominent example of collective action across WHO member states to address a significant public health problem worsened by

globalization. This required participation by a broad spectrum of national, regional, and global stakeholders. The mobilization of public health advocates worldwide, led by the Framework Convention Alliance, was greatly facilitated by the use of the internet (focused on the Globalink network) which enabled stakeholders to follow negotiations, organize advocacy activities, and share experiences (Collin et al. 2004). While the final treaty was weaker on some key challenges posed by globalization than initially hoped, such as setting aside tobacco from international trade agreements, the possible negotiation of additional protocols was to address these transboundary issues. To date, only the FCTC Protocol to Eliminate Illicit Trade in Tobacco Products has been signed, and will come into effect when ratified by 40 states parties (WHO 2015).

In summary, globalization has coincided with the rise of NCDs worldwide across diverse populations, posing new challenges for public health. In many cases, powerful vested interests within key sectors of the world economy oppose stronger action to prevent and control NCDs. Initiating collective action, such as the WHO Global Action Plan for the Prevention and Control of NCDs 2013–2020, can serve to make NCDs a higher priority. However, past experience shows that international agreements are only the starting point. Effective implementation of commitments requires sustained mobilization of political will, resources, and technical capacity to translate strategies into results (Ravelo 2018). A key lesson from efforts to date to address the risk factors of obesity and tobacco use in some countries, is that globalization needs to be better harnessed for health promotion. Worldwide consumer boycotts of TNCs, such as Nestlé and McDonalds, have been organized via social media by civil society organizations to pressure companies to change their practices (Swinburn et al. 2015). The public health community has also drawn attention to the dangers of illicit products through global campaigns (Fig. 1.5.2). These examples of collective action across societies, to harness globalization to counter continued high rates of tobacco use, obesity, and other risk factors behind the rising trends in NCDs, offer important examples to build upon.

Harnessing global information and communication technologies for public health

A defining and enabling feature of contemporary globalization has been rapid advances in information and communication technologies (ICTs), spurring the transformation of societies worldwide. From the personal computer in the 1980s, the progressive development of ICT devices with ever faster processing speeds and larger storage capacity has enabled a wide range of applications at affordable prices. Investments in ICTs not only generate economic impacts, they served as core infrastructure for the global economy as a whole. Global ICT networks underpin global supply chains, transportation systems, 24-hour financial trading and vital information networks (Baller et al. 2016).

The globalization of ICTs may lead to profound changes in the health sector including research, diagnostics, patient care, planning and management, informatics, and health promotion. Often known as eHealth (or electronic health), technological change has been spurred by the increased complexity of health systems, need to manage ever larger and more complex datasets, rising cost of healthcare, need to provide longitudinal and comprehensive health records for individual patients, and increased mobility

and/or geographically dispersal of many patient populations and healthcare providers. ICTs have been identified as particularly effective, for example, at reaching more individuals with effective health-related advice and information at a very low cost (Bloom et al. 2017).

The use of mobile and wireless technologies in health (known as mHealth), in particular, has grown rapidly with advances in technologies and applications (or 'apps'), the declining cost of handsets and data transmission, and growth cellular network coverage. According to the International Telecommunication Union (ITU), subscriptions grew 20% annually from 2012 to 2017, reaching 4.3 billion globally by 2018 (ITU 2017). LMICs have seen the highest rate of growth where the potential for mHealth to improve healthcare, hindered in the past by a lack of infrastructure, is most promising (Silva et al. 2015).

Social media, 'interactive platforms via which individuals and communities create and share user-generated content' (Kietzmann et al. 2011, p. 241), has also seen the blossoming of health-related applications. A systematic review of social media and public health messages finds that, as more consumers turn to the internet for health-related information, health organizations have begun to use social media for connecting with the public For example, health insurance companies are applying social media, health gaming apps, and other mobile apps to increase patient engagement in their own healthcare. Evidence suggests considerable reach associated with social media applications, and the potential for engaging specific target audiences, although efficacy of public health messaging requires further investigation through controlled studies (Ventola 2014).

Overall, ICTs offer much promise to enhancing core public health functions. There continues to be substantial investment in such technologies by the public and private sectors, and their application to a wide range of health applications. However, systematic reviews of the use of eHealth technologies in behavioural interventions (Oosterveen et al. 2017) and mental health (Stratton et al. 2017), for instance, cast doubt on the longer-term efficacy and cost-effectiveness of using such technologies.

Importantly, there has also been an increased use of ICTs for commercial purposes to shape consumer choices and behaviours. The online marketing, promotion and distribution of health-affecting products and services has spread rapidly and, in most cases, remain weakly regulated. The global reach of direct-to-consumer marketing of pharmaceuticals (genuine and

counterfeit), supplements, food and beverages, and tobacco products (including electronic nicotine delivery systems) via the internet has been a particular source of regulatory concern (Freeman et al. 2014). For national authorities, the challenge of regulating the internet arises from the global nature of ICTs. How to strengthen global regulatory mechanisms, notably in countries where such goods originate, has been the focus of growing policy debate (Institute of Medicine 2012). Collective action to regulate the global use of ICTs, to protect and promote population health, remains much needed.

Strengthening the governance of global public health

From international to global health governance

Governance broadly concerns the agreed actions, rules, and means adopted by a society to promote collective action and solutions in pursuit of common goals. Governance takes place whenever people seek to organize themselves to achieve a shared end through agreed rules, procedures, and institutions. This can take place at different levels of decision-making and action. In public health, if a local community decides to initiate a campaign to slow traffic speed and improve road safety, this requires some form of governance to organize the effort. If a national policy is adopted to improve food labelling and increase the taxation of unhealthy foods, governance is needed to set the agreed labelling standards and rates of taxation, as well as enforce compliance. If a global campaign is initiated to strengthen tuberculosis control, an agreed form of governance is needed to take decisions, for example, on agreed treatment, resource mobilization, and implementation of agreed actions across countries. To what extent is there need for more effective governance to protect and promote public health within an increasingly globalized context?

The existing institutional arrangements for collective action among countries have historical roots dating from the International Sanitary Conferences of the nineteenth century. This series of meetings, largely dominated by European countries and the US, focused on protecting their economic and political interests from epidemic diseases such as cholera and plague. The institutions eventually created, such as the *Office International d'Hygiène Publique*, were primarily concerned with collecting and disseminating epidemiological data on these diseases (Fidler 2001). The

creation of the WHO as a specialized agency of the United Nations in 1948 was intended to universalize membership, and broaden the scope of, international health cooperation. Its objective, 'the attainment by all peoples of the highest possible level of health', was reflected in the vast array of programmes initiated under WHO's auspices (Lee 2008).

Recent decades have seen challenges to WHO's designated role as 'the directing and co-ordinating authority on international health work' (WHO Constitution, Article 2(a)). In part, this has arisen from differences in perspective on whether WHO should be biomedically (disease) focused, or whether the organization should address the broad social determinants of 'health for all'. These debates have been accompanied by rapid changes in WHO's operating environment, with the ascendance of new institutional players with often competing resources, technical expertise, and normative perspectives (McInnes and Lee 2012). From the 1980s, the World Bank became a major influence as the biggest source of financing for health development (Buse 1994), while other UN bodies such as the UN Children's Fund and UN Development Programme (UNDP) expanded their health portfolios. The 1990s saw the creation of numerous global public–private partnerships for health which attracted additional resources, but rendered the policy environment far more complex and crowded (Buse and Walt 2000). Charitable foundations, led by the Bill and Melinda Gates Foundation, have since become the biggest players in the funding of health development (Birn 2014). This influx of institutions and resources has, on the one hand, reflected the higher priority to health development given by governments, corporations, and civil society organizations (CSOs). On the other hand, there is substantial evidence of overlapping mandates, duplication of effort, and, above all, a lack of consensus about how to effectively tackle the collective public health challenges posed by globalization (Gostin 2017).

The governance of global public health can thus be understood as undergoing a period of transition, from international (state-based) to global (state and non-state-based) collective action. In principle, leading institutions formally responsible for governing public health remain governmental. Public health authority lies within the ministries of health of each WHO member state, and collaboration across countries and regions is expected to take place on a wide range of functions through governmental bodies. However, as described in this chapter, intensified flows of people, other life forms, goods and services, capital, and knowledge are creating

transboundary health determinants and outcomes that can transcend state capacity to manage them. This is due, in part, to differences in perspective about what priority goals and actions should be pursued, the capacity of governments to act, and even a willingness to act collectively. Where governments cannot or will not assume a global health governance role, non-state actors in the form of CSOs, charitable foundations, and even corporations have been looked to as potentially filling this governance gap. Many scholars of global governance point to the need for new institutional arrangements to enable more effective action in the face of urgent need. Examples described in this chapter—such as tobacco control, obesity, and infectious disease outbreaks—demonstrate the need for innovation but also the political challenges posed.

Strengthening legal and regulatory frameworks for global health

Globalization is now an established subject of discussion and debate at public health meetings around the world, and there has been no shortage of commitments to addressing its impacts. Efforts to do so through stronger regulatory frameworks have yielded mixed results. The FCTC is seen as a successful example of WHO member states coming together to address a major global public health problem through the creation of a legal instrument requiring signatories to adopt a minimum package of measures. The revision of the IHR in 2005 was also an important step towards the creation of legal frameworks for global health groups (GHGs). Collective action was furthered on access to medicines through the 2001 Doha Declaration on Intellectual Property Rights and Public Health, followed in 2003 by the WTO's Decision on Implementation of Paragraph 6, both intended to clarify flexibilities in the Agreement on Trade-Related Intellectual Property Rights permitting member states to take measures, such as compulsory licensing, that improves access to medicines (Kerry and Lee 2007). The Report of the WHO Commission on Intellectual Property Rights, Innovation and Public Health (WHO 2006b) sought to address the tensions between economic and health equity goals by reviewing 'current incentive and funding regimes, including intellectual property rights, designed to

stimulate the creation of new medicines and other products, and facilitate access to them' (p. iv).

Beyond the health sector, however, to what extent is there recognition of the need to govern globalization differently? The foremost challenge, perhaps, remains the governance of the world economy in ways that are ecologically sustainable, and bring the most benefits to the most people. The global financial crisis beginning in 2007 revealed fundamental regulatory weaknesses—the availability of easy credit, incentives to undertake high-risk lending and borrowing, poor fiscal management by governments, and rampant speculative investing. The reforms that followed have sought to 'fix' selected parts of the global financial system. However, critics argue that the parts addressed are those which enable the 'haves' in the global economy to have more. The further concentration of global wealth in ever fewer hands —1% of the world's population owned 50% of global wealth by 2017 (an increase from 42.5% in 2008)—sharply questions the social, political, and environmental sustainability of current forms of economic globalization (Credit Suisse 2017). The rise in populist movements worldwide, many opposing globalization, reflect this discontent.

In relation to public health, more fundamental reforms in the governance of the global economy are required which recognize the profound consequences of insecure employment, stark inequalities in wealth, large-scale corporate tax evasion, and environmental degradation on human health. As heads of state, ministers of trade and investment, and corporate executives ponder the future of economic globalization, the public health community can seek to play a bigger role in creating the necessary checks and balances for the global economy to function sustainably. Public health representation in policy debates on trade and finance to date has been limited. WHO, public health institutions, and civil society organizations have remained at the margins of key decision-making forums such as the WTO, World Economic Forum and Group of Seven (G7) meetings. The substantial concerns by citizens and consumers worldwide about the social and environmental footprints of global products and services, the looming economic time bomb of NCDs, and the potential costs to the global economy of a highly lethal infectious disease pandemic may be leverage points for finding common ground between public health and economic policy. A global public goods for health approach, for example, addresses globalization and health from an economic perspective. The concept

identifies where a good or service (such as knowledge of an infectious disease outbreak), which would be of benefit globally, will not be produced or disseminated if left to the market because no one can be excluded from accessing the good, and thus no charge can be levied for its use and no costs recouped. There may even be economic disincentives to produce certain goods, such as outbreak reports, because of resultant negative economic consequences. At the national level, the production of these goods is usually ensured by government intervention, but at the global level there remains no 'global government' to undertake this role. Certain functions of public health may be classed as global public goods (e.g. immunization programmes, disease surveillance), which require collective action to overcome market failures (Smith et al. 2005). The concept might thus be an appealing rationale to non-health policymakers shaping global change. The potential role of health impact assessment for informing policy proposals is another such approach (Friedman and Burci 2017). Most importantly, the long-term sustainability of globalization requires public health to be a core part of any efforts to build better global governance.

Conclusion

This chapter has described key ways in which globalization is relevant to the theory and practice of public health. There are both risks and opportunities arising from the complex and diverse changes being created by globalization, with current forms of market-dominated globalization characterized by an inequitable distribution of winners and losers. For the public health community, there is a need to understand and contribute to more effective management of the rapid changes taking place. Greater attention to these public health impacts will, in turn, contribute to more sustainable forms of globalization.

Determinants of health

Overview

Matthew Fisher, Belinda Townsend, Patrick Harris, Ashley Schram, and Fran Baum

Introduction

Determinants of health have been defined as ‘the range of personal, social, economic and environmental factors which determine the health status of individuals or populations’ (Nutbeam and World Health Organization 1998). An understanding of determinants of health accepts that human health is affected by multiple factors operating at different levels and interacting in complex ways. Determinants of health are classically grouped into four categories of biological, behavioural, environmental, and social determinants (Remais and Jackson 2016), although other classifications are available which incorporate categories such as ‘knowledge, attitudes and beliefs’ (Australian Institute of Health and Welfare 2008). Determinants of health are understood through a combination of research methods, investigating associations between specified factors and disease or disease risk in populations, and investigating mechanisms by which particular factors affect the health status of individuals (Rose 1985).

Biological determinants

Biological determinants are endogenous features of the human body that affect health. They include the genetic structures that play a central role in the development of body and brain in early life and may render a person more or less susceptible to particular diseases. Age is also identified as a biological determinant of health recognizing, for example, that deterioration of cell functions in old age may increase susceptibility to disease. Arguably,

the category of biological determinants is limited by its attention on physical attributes and overlooks the role that neuropsychological states play in affecting health; a matter we will discuss further later in the chapter.

Behavioural determinants

Behavioural determinants notably include the widely recognized ‘lifestyle’ factors of tobacco smoking, use of alcohol and other drugs, and diet and exercise. Tobacco smoking is known to increase risk of a range of respiratory and cardiovascular diseases and several forms of cancer, and contributes to around six million premature deaths globally each year (World Health Organization 2015). Diet and exercise affect health in a range of ways, but most notably influence the development of overweight and obesity, which increase risk of conditions such as type-2 diabetes, cardiovascular diseases, musculoskeletal disorders, and some cancers. Prevalence of obesity worldwide had tripled since the 1970s, and represents a growing risk to health in many countries (World Health Organization 2017). As we discuss later, this category is regarded by some as too limited because it overlooks the role that social and commercial factors play in influencing health behaviours (Baum and Fisher 2014).

Environmental determinants

Environmental determinants are factors in the physical environment that affect health, including features of human-made environments such as air pollution or availability of sewerage systems, and feature of natural environments such as weather events, insect-borne disease vectors, or availability of fresh water. The characteristics of foods such as their nutritive properties or presence of food-borne pathogens are important environmental determinants of health. For example, a lack of naturally occurring iodine in soil—and thus in the food it grows—impairs mental function in adults and during pregnancy can compromise foetal development. Diarrhoeal disease caused by contaminated water or food is a major cause of illness or death in children under 5 years, especially in low-income countries (LICs). Clearly, human activities are increasingly shaping ‘natural’ environments in a variety of ways with implications for human and ecological health such as land clearing and agriculture, commercial fishing, and use of fossil fuels

contributing to global warming. Air pollution is an environmental determinant of growing concern. Recent analysis from the World Health Organization (WHO) indicates that each year around 4.2 million deaths result from ambient air pollution and 3.8 million deaths from household air pollution from cooking fuels (World Health Organization 2018).

Social determinants: an introduction

Social determinants of health (SDH) have been defined as including both the daily social and economic conditions in which people live, and the higher-level socioeconomic and political factors that affect distribution of power, money, and resources, within or between countries (Commission on the Social Determinants of Health 2008). Factors in daily life that affect health include living and working conditions, availability of healthy foods, and access to healthcare. The higher-level factors, such as the decisions of governments or the structures of a market economy, are understood to *distribute* the social conditions that positively or negatively affect health; working through key mediating mechanisms of power, income/wealth, education, and employment (Commission on the Social Determinants of Health 2008). Where these processes produce inequalities in access to conditions supportive of good health, or in exposure to conditions that adversely affect health, then (socially determined) inequalities in health are the likely result. For example, political and economic conditions within a particular country may be such that relatively wealthy, urban populations enjoy better access to good quality food, medical care, and housing than impoverished rural populations, leading to higher rates of infant mortality in the latter group. This multilevel understanding of SDH is illustrated in Figure 2.1.1.

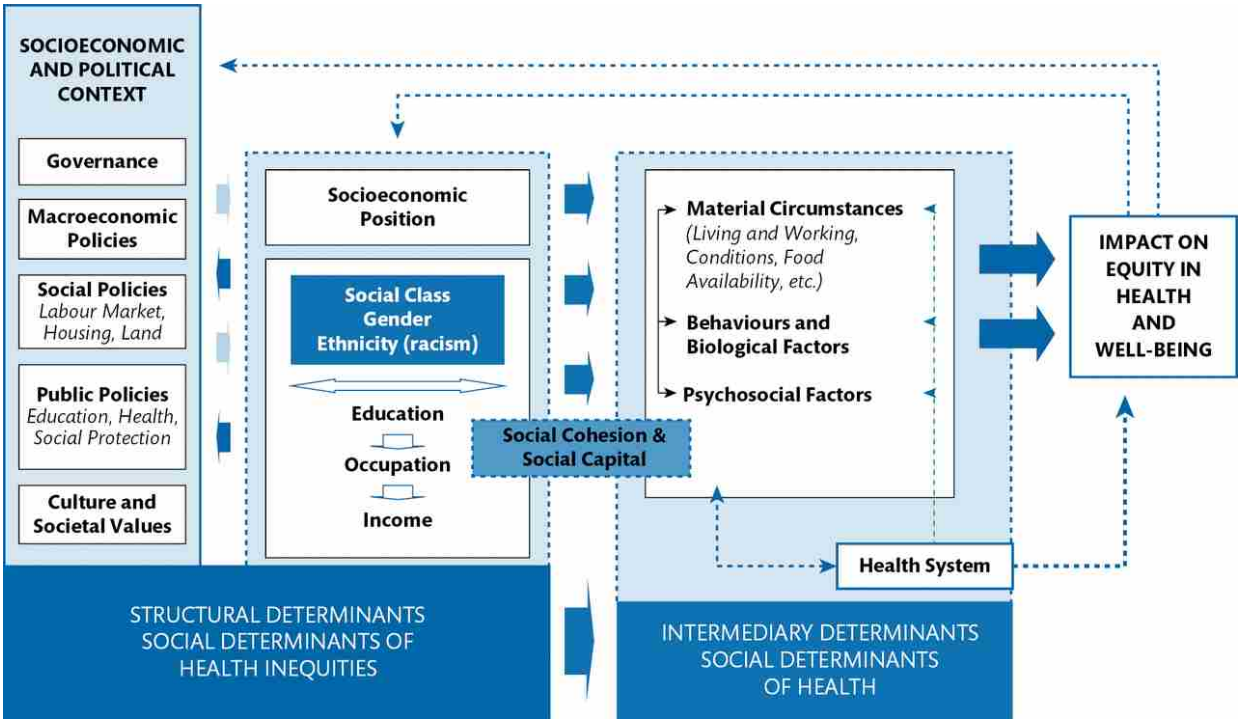

Fig. 2.1.1 Social determinants of health and health inequities.
Adapted with permission from Solar, O. & Irwin, A. (2010). A Conceptual Framework for Action on the Social Determinants of Health: Social Determinants of Health Discussion Paper 2. Geneva: World Health Organization. Copyright © 2010 WHO.

Not all health inequalities between populations are socially determined. Women have much higher rates of breast cancer than men but this is thought to result from biological differences, rather than differences in social conditions. (However, equally, socioeconomic factors may determine that some women have access to screening or treatments for breast cancer while others do not.) Health inequalities that *are* understood as socially determined may also be regarded as unfair or unjust. Those taking this view argue that health inequalities arising from structural social and economic inequalities could be reduced or eliminated, if governments and societies made different choices. To not do so, then, is regarded as unfair to those who (unnecessarily) are subsequently subjected to higher rates of disease and shorter lives than others (Whitehead 1992). Those who accept such arguments may refer to socially determined health inequalities as ‘health inequities’ (Baum 2016) to signal their ethical stance; a position we will adopt in this chapter. Such arguments can appeal to evidence showing that across different countries both overall health outcomes and the extent of health inequalities vary widely, in ways that relate to differences in political,

social, or economic conditions (Commission on the Social Determinants of Health 2008). In the next section we discuss some commonly identified SDH in more detail.

Social determinants of health

Many features of human societies are identified as SDH (Marmot et al. 2008). Here we discuss some standard items in classifications of SDH and some issues that have come to prominence more recently, as shown in Table 2.1.1. It is useful to note that there are different pathways and mechanisms by which social factors get 'under the skin' to affect individual or population health. Some of these are predominantly physical in nature, such as poor working conditions in mining leading to exposure to dust, contributing to lung disease. Other pathways involve psychological states. In particular, recurrent exposure to social environments perceived as threatening or demanding can cause psychological distress and chronic arousal of stress physiology, leading to adverse effects on mental or physical health (Fisher and Baum 2010).

Table 2.1.1 Social determinants of health

• Healthcare services	• Determinants of mental health
• Environments for early child development	• Urbanization and health
• Income, education, and employment status	• Globalization and commercial determinants of heath
• Employment conditions	• Social determinants of health behaviours
• Gender	• Climate change and SDH
• Social and cultural determinants of Indigenous health	• Distribution of power and resources

Healthcare services

Access to healthcare services is widely recognized as an SDH, supporting health and preventing disease by providing trained advice and support, preventative interventions such as vaccination, and medical treatments for disease or injury; when these are needed. Research suggests that universal access to primary healthcare (PHC) is an important step in improving population health and health equity in all countries (World Health Organization 2008). A comprehensive approach to PHC combines first-level medical care with strategies to promote health, prevent disease, engage communities, and address other determinants of health within local spaces (Baum 2016).

Environments for early child development

Environments affecting the early emotional, cognitive, behavioural, and physical development of children, say from conception to 7 years of age, are crucial in determining health prospects over the life-course (Irwin et al. 2007). Social factors involved here include: access to material resources during pregnancy to promote good health; opportunity to undertake and continue breastfeeding; nurturing and stimulation; interaction to develop socialization and language; housing conditions; and access to clean water (Maggi et al. 2010). Higher-level economic and social policies shaping issues such as minimum wages, parental leave provisions and welfare provision, or inequalities in income, differentially affect the lives and circumstances of families and other proximal conditions of child development, contributing to inequities in child health (Irwin et al. 2007).

Income, education, and employment status

These three factors are central to contemporary understanding of SDH and health inequities within and between countries (Baum 2016). Clearly they are related: for example, education is likely to affect employment status, which affects income, which in turn affects educational opportunities across generations. Income, education, and employment are key mechanisms by which hierarchical societies distribute resources, thereby affecting differences in living and working conditions, and ability to afford essential goods and services. Some evidence suggests that, in addition, the psychological experience of being in a lower position within a status

hierarchy can itself have adverse consequences for health (Wilkinson and Pickett 2009). Income, education, and employment status are commonly used as measures of socioeconomic status (SES), and research shows that health inequities do not just manifest as poorer health among those at the 'lowest' end of the SES scale, but often follow a gradient pattern whereby average health status decreases incrementally at each step down the SES scale, from 'highest' to 'lowest' (Fryers et al. 2003; Marmot and Friel 2008). Furthermore, among developed countries those with higher levels of inequality tend to have worse health across all SES levels, compared to more equal societies (Wilkinson and Pickett 2009). Thus, arguably, social and health inequities are a concern for all. Figure 2.1.2 presents an example of social gradients in child mortality within five countries. Note that there are also inequities between these countries.

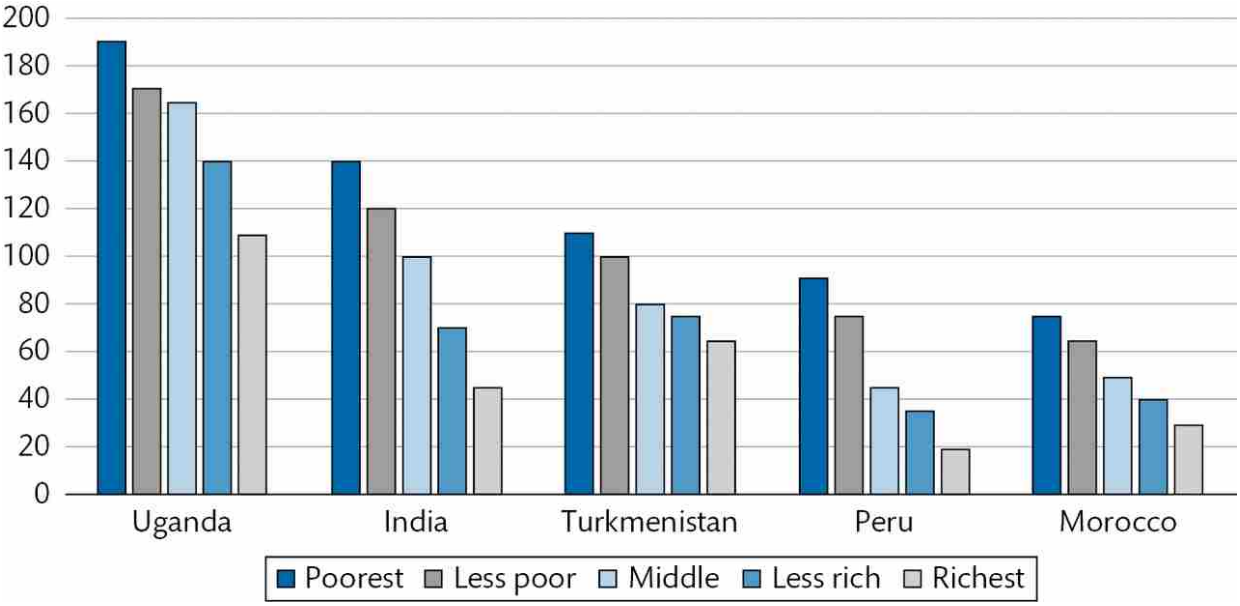

Fig. 2.1.2 Under-5 mortality rate per 1000 live births by level of household wealth in five countries, between 1998 and 2004.

Employment conditions

Aside from the role of employment in determining SES, the conditions of employment and unemployment are also important SDH. Work may provide many benefits for health, including financial security, social relationships, a sense of purpose, and opportunities for learning. However, workplace conditions may also involve exposure to health-damaging substances, physical demands causing injury, or psychosocial demands causing chronic stress (Marmot et al. 2008). In many countries the nature of work is changing under pressures from (inter alia) globalization, neoliberal 'austerity' politics, financial crises, technological change, declines in trade unions, and growth in casual and informal work and self-employment. Economic inequalities between countries create incentives for permanent or temporary migration to seek work, and these workers may be at higher risk of exploitation. According to the International Labour Organization (2015), in 2013 around 150 million people migrated for reasons of work. These changes risk an expanding divide between the 'haves and have-nots' in work status, security, and remuneration—within and between countries—with the potential to exacerbate health inequities.

Gender

In most parts of the world women tend to live longer than men despite reporting more ill health. Explanations for women's longer lifespans have included biological differences, the more dangerous nature of male employment, the tendency for women to seek healthcare more readily, and the greater social attachments women have (Baum 2016). However, gender inequities unfavourable to women have a range of adverse impacts on health by placing women and girls in cultural, social, or economic positions of lesser status compared to their male counterparts. Gender inequities affect health in a variety of ways, contributing to violence against women, discrimination against female children, unfair divisions of work, lower wages, and restricted access to education and healthcare (Marmot et al. 2008).

Social and cultural determinants of Indigenous health

Indigenous peoples are defined as the descendants of 'those who inhabited a country or . . . region at the time when people of different cultures or ethnic origins arrived, [who then] became dominant through conquest, occupation, settlement or other means' (United Nations Permanent Forum on Indigenous Peoples 2018). Although data on the health status of Indigenous peoples is uneven, in countries where it is available the story is often the same: Indigenous peoples have significantly worse health than the non-Indigenous population (Anderson et al. 2016). While Indigenous health is no doubt influenced by 'general' determinants such as income, scholars now identify a range of determinants affecting Indigenous peoples more particularly. These include health-promoting factors such as strong cultural identity and community control over resources and, on the negative side of the ledger, processes of colonization such as dispossession of traditional lands, discriminatory policies such as removal of children, and exposure to racism (Carson et al. 2007).

Determinants of mental health

Common forms of mental illness (including substance abuse disorders) account for around 20% of the total global burden of disease in terms of years lived with disability (Whiteford et al. 2013), equating to many millions of people whose ability to gain an education, keep a job, or maintain social relationships may be compromised. Depressive disorders alone are a major and growing cause of disease burden globally and contribute to the approximately 800,000 suicides that occur each year. Many of the SDH we have discussed may adversely affect mental health by causing chronic stress (Fisher and Baum 2010). Social factors affecting use of alcohol and other drugs also play a significant part. Chronic physical ill health may also contribute to poor mental health. Major events such as wars or natural disasters are likely to have significant impacts on stress and mental health by destroying basic infrastructure and causing dislocation of populations. As with other health conditions, rates of common forms of mental illness are typically inversely related to SES (Fryers et al. 2003).

Urbanization and health

A growing proportion of populations globally and within countries are living in cities. In 2008, for the first time in human history, the majority of the world's population lived in urban environments, and the decade since has seen an upsurge in interest in the links between cities and health. There is now broad acceptance that urbanization itself is a determinant of health and of health inequities within and between urban populations.

To understand urbanization as a determinant of health, there is now evidence of the full causal chain from urban system policies to health outcomes such as injuries, respiratory diseases, stress and mental illness, and infectious disease; and to quality of life outcomes such as well-being and liveability (Giles-Corti et al. 2016). Risk exposures cluster around environmental conditions (air, noise, and traffic), human factors (social isolation and safety), and behaviours (healthy eating, physical activity) (Giles-Corti et al. 2016). Although these factors have tended to be described as health-related features of the 'built environment', health is also affected by the social and economic make-up of cities. Here it is important that basic goods such as sanitation, education, healthcare, and social services are provided in ways, 'that are socially cohesive, that are designed to promote good physical and psychological well-being and that are protective of the natural environment' (Friel et al. 2011, p 863). At the same time it is now understood that urbanization is in large part contributing to global issues like climate change and migration.

In terms of action, the alignment of the determinants of health within urban planning policy systems is crucial. A century ago planning was strongly aligned with public health objectives to prevent the spread of infectious disease. This close relationship was not sustained, however, as planning became a specific policy sector in most developed countries with narrower aims related to setting strategic direction for cities, assessing and approving developments, and other local issues to do with zoning and urban design. While planning and public health are gradually realigning, full realization of the potential of urban planning to prevent disease and reduce health inequity requires substantial shifts in the policy systems that govern the built environment (Friel et al. 2011). From an SDH perspective, the challenge is to align the broad interests of a public health agenda with those of urban planning—tricky in countries where there are well-developed urban planning sectors, and even more difficult in resource-poor settings where regulatory frameworks governing city planning may not exist. Evidence on

health impacts alone is unlikely to suffice given that city planning is closely linked to competition between cities globally and thus is strongly influenced by local politics and perceived economic imperatives. Rather than prioritizing health, concepts like ‘agglomeration’ have come to dominate urban planning, whereby urbanization creates local centres for production activity that require servicing to function effectively. However it is important to recognize that considerations of health and economic vitality are not incompatible, given that well-planned cities that are more liveable and equitable in terms of offering jobs, goods, and services are likely to be more competitive economically.

Questions of scale ought to dominate thinking about urbanization as a determinant of health. Urbanization itself is uneven across countries even as cities become central to the global economy; massive slums dominate some cities and can even exist alongside affluent suburbs, whereas others are characterized by urban sprawl. Within cities the need to plan at varying scales is fundamental to managing urbanization and population growth at regional and city levels down to local places and spaces. These issues of scale are replicated in the various governance arrangements that dominate how cities are developed and planned. Local government has long been recognized as politically powerful, for instance by the Healthy Cities movement, and the ‘local’ scale is seen by some as an important venue for action on SDH and health equity, able to mitigate some effects of determinants operating at a national or global scale. There are also a range of actors—public and private—engaged in planning for and delivering urban environments ranging from large city-wide infrastructure projects to precincts to buildings. Action to ensure these varying governance regimes and networks continue to engage with ideas about urbanization as profoundly influencing health are essential.

Globalization and commercial determinants of health

Globalization facilitates increasing interconnectedness between national economies, societies, and cultures, shaping the upstream determinants of health. Arguably, globalized economic activity has produced some benefits for health through increased living standards, although this proposition is contested (Baum 2016). However, globalization has also facilitated widening income inequality. Income inequality has increased in nearly all regions of

the world over recent decades, although at different speeds (Alvaredo et al. 2018). Globalization therefore presents risks and challenges for population health and health equity within and between countries.

In the last two decades, intensified movement of capital and expanded trade and investment has facilitated the growth and size of transnational corporations (TNCs); those firms with manufacturing, production, and marketing operations across multiple countries. TNCs like Coca-Cola have production sites on every continent and extensive supply chains across the world. TNCs have also become significant economies on their own. In 2016, of the top 100 world economies, only 31 were countries. Most of the world's largest economies are now TNCs such as Walmart, Royal Dutch Shell, and Exxon Mobile, and technology firm Apple.

TNCs have become powerful actors, with significant economic resources, influencing global policymaking. For example, global pharmaceutical firms played a key role in shaping the World Trade Organization's *Trade-Related Aspects of Intellectual Property Rights Agreement* (TRIPS) which requires signatories to provide a minimum of 20-year protections on patents (Sell 2003). TNCs, alongside other industry bodies, have pushed for an expansion of the issues covered under trade and investment agreements between countries. While trade agreements once covered commitments to reduce tariffs, they increasingly include rules for domestic regulatory issues, such as intellectual property, competition, technology, and rights for investors.

There are several pathways through which these trade agreements can impact on health. Trade agreements can have a positive effect on health through increased access to technologies and health-promoting products and services. But they can also create negative consequences. The extension of intellectual property rights in trade deals, for example, can delay the market entry of cheaper generic medicines, reducing affordable access (Townsend et al. 2016). Trade agreements also promote greater market liberalization which facilitates the availability, affordability, and accessibility of unhealthy commodities such as ultra-processed food, tobacco, and alcohol—three key risk factors for non-communicable diseases (NCDs). Simultaneously, these agreements secure greater access for TNCs in domestic regulatory policymaking, which can increase the time and resources required for governments to regulate these products, as well as the influence of industry on the selected regulatory approach (Schram et al. 2017). Trade deals can therefore serve as enabling mechanisms for the commercial drivers of

NCDs. The costs associated with the negative effects of products such as cheap ultra-processed foods (most significantly an increase in NCDs) is externalized to governments.

The ‘commercial determinants of health’ is a recent term in public health used to refer to the practises and strategies of corporations involved in driving risk factors for NCDs (Kickbusch et al. 2016). In addition to influencing trade and investment deals, companies that manufacture and trade in unhealthy commodities such as tobacco, alcohol, and ultra-processed food utilize a number of strategies to promote greater uptake of their products and undermine public health regulation. Documented strategies by firms include marketing strategies targeting young people, lobbying, and donating to political representatives, partnering with governments, funding biased research, co-opting health professionals and policymakers to promote industry objectives, and sponsoring campaigns to favourably influence public opinion (Kickbusch et al. 2016). The regulation of unhealthy commodities industries has therefore become a key challenge for global public health. Public health researchers have criticized the continuing participation of alcohol and food industries in global health policymaking. For example, despite strong financial motivation to promote the consumption of sugary drinks, Pepsi-Co and Coca-Cola contributed to the recommendations of the 2011 UN High-Level Meeting on NCDs (Buse et al. 2017).

Public health campaigns have successfully intervened in the commercial determinants of health, most notably in tobacco control. Following decades of collecting and disseminating evidence and advocacy from health practitioners and policymakers, the first global treaty on tobacco—the WHO *Framework Convention on Tobacco Control* (FCTC)—was adopted in 2003 and has since been ratified by 181 countries. The FCTC explicitly prevents parties from engaging with tobacco companies, and offers a strong example of regulation to prevent industry interference. The case of tobacco illustrates that public health advocacy can be channelled to counter industry power and profits.

Social determinants of health behaviours

Ultimately, improving the health of populations may require changes in behaviour. On the face of it doing this appears relatively straightforward, in

that there are a range of behaviour change techniques to assist. However, behaviours are socially structured and so it follows that changing these behaviours requires changing the structures within which behaviours occur. Despite mounting evidence to support the importance of structure in shaping behaviours, behaviourism is still often promoted as a solution to 'lifestyle' diseases while paying little attention to structures. Ideologies influence these policy choices, as Tesh (1988) noted some time ago. Her analysis of US public policy demonstrates that there is a strong ideology of individualism which undermines appreciation of the role of structural factors, meaning that behaviourism is often privileged despite a weak evidence base for its effectiveness. There is a strong inherent logic to behaviour change strategies (Baum and Fisher 2014). If the problem of smoking is seen as one of people choosing to smoke and obesity as one of people overeating, then telling them not to do this seems to make sense.

There are many theories grounded in social psychology which aim to assist individuals to change their behaviours. These include social learning theory (Bandura 1977) and the health belief model (Becker 1974). Each tackles individuals' underlying beliefs and their motivations to change their behaviours. Such theories underpinned a generation of heart health programmes in the 1970s and 1980s. These started with great promise but in the main have been shown not to be successful. Their major limitation is that these models pay scant attention to the social, economic, and cultural environments in which people's behaviours occur. One of the few heart health programmes to succeed was the Finnish North Karelia programme. Its evaluation reported greater changes in chronic heart disease (CHD) risk factors than for the Finnish population as a whole, and in CHD male mortality (Puska et al. 2009). The relative success in North Karelia was not mainly a result of individual increase in health knowledge, but rather of community-level strategies—including provision of PHC services and involvement of community organizations—and policy changes, such as the reduction of fat in food.

The accumulated experiences with unsuccessful health promotion programmes directed at individual behaviour change reinforces the importance of the social determinants of behaviour. Many behaviours judged to be bad for health are often those that help people cope with stressful circumstances or are simply a response to an unhealthy environment. Thus the high smoking rates among Australian Aboriginal people reflect, in part, a

means of coping with the racism they experience in their daily life. The increase in overweight and obesity is primarily because the marketing and supply of high fat and sugar foods in many countries has made these foods attractive, available, and affordable. As we saw in the previous section, trade agreements have made it much easier for transnational food companies to gain access to food markets and undermine healthy food supply. Thus individual behaviours reflect social, cultural, economic, and physical environments in which people live. Changing behaviours requires changing these environments.

Changing environments is particularly important in achieving health equity. Behaviour makes the most difference to people's health status when other conditions in their life are favourable. So, if someone is not poor in relation to the society they are living in, if they are not living in absolute poverty, have a supportive social network, are reasonably free of disease, then behaviour change strategies might make some difference to their health status; but such strategies alone are likely to increase rather than decrease health inequities.

Climate change and social determinants of health

Anthropogenic global warming leading to climate change is having significant, adverse effects on human health that are only likely to increase in the future. While climate change is an environmental rather than a social determinant of health, human societies as currently configured are the primary cause of global warming, and the effects of climate change also intersect with SDH in ways that significantly shape health and health equity outcomes (McMichael 2017). Climate change can adversely affect health in a variety of ways including: the frequency and intensity of extreme weather events; sea level rise and associated flooding in low-lying islands or coastal areas; changing vectors of contagious disease; loss of arable land; and reduced access to fresh water. In many cases the health impacts of these events are likely to fall most heavily on countries, and population groups within countries, that are also subject to socially determined health inequities. Social impacts of climate change include the possibility of environmental refugees, forced to move in response to extreme weather events or changed environmental conditions, who will be highly vulnerable to poor health. Health impacts of climate change may also increase demand

on under-resourced healthcare systems in LICs. For all these reasons, climate change—intersecting with SDH—presents risks of increased health inequities globally and within countries over time.

The complexity of determinants and their interactions

The complex and multiscaled nature of determinants of health presents a number of complications for understanding and action, whether by researchers, healthcare practitioners, civil society organizations, governments, or international agencies.

Temporality

In epidemiology, the concept of relative risk is used to express a causal link between a particular social or environmental determinant and the health of an individual or population group: that is, the likelihood or risk that people exposed to condition *x* will go on to develop disease *y*, relative to others not exposed. For example, in Australia, a current smoker is nine times more likely to develop lung cancer than a non-smoker. However, these equations on their own do not convey the temporal nature of the relationships between determinants and health or disease (Remais and Jackson 2016). A clinically recognizable effect on health arising from exposure to a particular determinant may take years to emerge. Exposure of young children to abuse or neglect is understood to increase the risk of conditions such as depressive disorders, drug use, and sexually transmitted infection (Norman et al. 2012), but these conditions generally develop in adolescence or adulthood. Along the way, other mediating factors may intercede to mitigate or exacerbate the risk. This kind of life-course perspective offers significant potential for primary prevention of multiple health problems, and possible gains in health equity, by acting on the common, underlying risk factor of child maltreatment (Irwin et al. 2007). However, for researchers, long time-lags between exposures and health effects complicate the challenge of investigating and demonstrating the links (Remais and Jackson 2016).

The dynamic, temporal nature of the relationships between determinants and health are also expressed over longer periods, and at larger scales. A combination of improvements in medical care, urban environments, nutrition, and living conditions is likely to have contributed to the so-called

epidemiological transition in many countries, where rates of infectious diseases (IDs) have declined, while NCDs have increased (Wahden 1996). In part, the increased prevalence of NCDs is a by-product of longer lifespans and ageing populations; because incidence of NCDs (such as heart disease and cancer) increases later in life. However, IDs do not go away, and may continue to have significant, adverse impacts among populations subject to disadvantage, producing what has been referred to as a 'double burden of disease', while having only small effects on overall population health (Wahden 1996).

Multiple scales and multiple determinants

As was alluded to earlier, relationships between determinants of health and health problems can be understood as spanning multiple mechanisms and events operating at different scales; from individual biology, psychology, and behaviour to social or environmental conditions at a local, national, and international scale. This understanding is represented in the nested models of SDH presented in the literature, such as Dahlgren and Whitehead's famous 'rainbow' model (2006). Thus, the health status of a particular individual or population group at any point in time is very likely to have been shaped by multiple factors. This presents challenges for research because more factors affecting health will be drawn into consideration, the farther 'out' from individual biology and behaviour one looks. The link between smoking (as a behavioural determinant) and risk of lung cancer can be established fairly readily, but if we ask why one population group has a smoking rate of 20% and another a rate of 5%, the determinants to consider expand accordingly. The nested nature of SDH also presents challenges for action. Healthcare practitioners seeking to reduce smoking rates might find it easier to focus on approaches targeting individual behaviour change such as nicotine therapy or health literacy, rather than worrying about broader determinants such as the lobbying practices of tobacco TNCs (Remais and Jackson 2016). Policymakers aiming to address increased rates of type-2 diabetes linked to obesity might find it easier to implement a social marketing campaign encouraging healthy food choices, than to tackle powerful interests determining the availability and marketing of ultra-processed, energy dense foods. The general argument from an SDH perspective is to look 'upstream' from biology and behaviour and address the higher-level environmental and

social determinants, the ‘causes of the causes’ (Commission on the Social Determinants of Health 2008); because they are the key to prevention rather than cure, and because even modest changes in social or environmental factors operating across whole populations will produce far larger gains for population health than interventions with high-risk individuals (Rose 1985).

In response to the complexity of social determinants, integrative theories have been put forward, explaining how the many factors, operating at different levels interact to produce health inequities. For example, Singh-Manoux and Marmot (2005) argue that health inequities are socially produced (and reproduced) via processes of ‘socialization’, whereby social class positions people within certain social milieu, which shape their psychology, attitudes, behaviours, and living conditions related to health.

Cross-boundary effects

Understanding environmental and SDH means that questions about the role and responsibilities of national governments cannot be avoided (Commission on the Social Determinants of Health 2008). However, it is also the case that many public health issues transcend national borders and policies and require processes of global governance (Marmot et al. 2008), presenting challenges to international organizations such as the United Nations and its health body the WHO. No public health challenge exemplifies this level of international and global concern more than the profound and entrenched social and economic inequalities within and between nations (Alvaredo et al. 2018), which are the underlying cause of health inequities. Similarly, climate change is surely a matter of global concern requiring a global response, including not just the obvious imperative to reduce greenhouse gas emissions but also consideration of the potentially complex repercussions of national policy responses. For example, policy decisions by wealthy nations to increase use of bio-fuels may create incentives in LMICs to shift agricultural production from food crops to bio-fuel crops such as palm oil. This in turn can lead to increased prices for food staples on global markets, contributing to undernutrition among people with lower incomes (Remais and Jackson 2016).

Another major public health issues transcending national boundaries is the movement of migrants and refugees across borders, whether stimulated by the desire to find work or to escape oppression or the violence of war. It is

estimated that the Syrian civil war alone has led to over 5 million refugees leaving the country and another 6 million people displaced within Syria. The repercussions of these events for health will inevitably be substantial and long-lasting, in Europe and the Middle East, and around the world.

Political challenges

National governments now operate within a global, neoliberal economic environment that prioritizes free trade, private profit, and economic growth and promotes these as vehicles for meeting human needs and reducing poverty. In this context, the role and capacity of national governments to regulate markets in ways conducive to public health, or tax and spend to deliver universal public services that contribute to health may be compromised in a variety of ways. Depending on the political and economic circumstances of the country in question, these challenges may take a variety of forms: governments adopting neoliberal or antidemocratic political values, weak or stagnating public revenues, influence of the private sector on policy, out-migration of skilled workers, or domestic political corruption just to name a few. Here we discuss two challenges for national governments in low, middle, and high income countries in taking action on SDH to improve public health and reduce health inequities.

Economic growth

The Preston Curve (Bloom and Canning 2007) indicates that, for LICs in particular growth in national income from a low base is often associated with marked increases in average life expectancy (although the benefits decline as national income continues to increase). Such health gains may well be influenced by improvements in determinants such as nutrition, access to clean water and safe sanitation, and PHC (Bloom and Canning 2007). The pathway to economic growth for LICs—as perceived by a national government, or promoted by international agencies—has commonly been seen as one of foreign investment for industrialization of mining, agriculture, or manufacturing for export, facilitated by low labour costs, urbanization, fossil fuel-based electricity generation, limited regulation and environmental protections, or tax concessions (Remais and Jackson 2016). Development loans to LICs from agencies such as the World Bank and the International

Monetary Fund have cultivated this approach by imposing conditions of economic liberalization and reduced government spending. However, this neoliberal model of development may involve adverse changes in determinants of health and health equity such as: poor nutrition or reduced access to healthcare; increased income inequalities; environmental degradation and pollution; poor urban living conditions; low wages and poor working conditions; displacement of population groups; and loss of agricultural production to meet domestic need.

Healthy public policy

The accumulated evidence on SDH along with a concern for health equity leads compellingly to the conclusion that health as a policy concern cannot be confined to the health sector alone but should involve all sectors and levels of government (Marmot et al. 2008). Such thinking has led to innovative strategies such as the 'Health in All Policies' approach in South Australia and elsewhere (Baum 2016). However, calls for a whole-of-government approaches to health face both institutional and political obstacles. On the former point, one issue identified is the 'siloed' structure of large government agencies, meaning the structures of decision-making, funding and accountability are organized vertically within departments and thus discourage 'horizontal' collaboration. On the political front, a raft of incentives may come into play encouraging decision makers (despite the evidence) to adopt a narrow biomedical and behaviourist view of health and illness, and thus focus their policy attention for 'health' on systems of acute care for illness, or on individualized, behaviour change strategies such as social marketing. As noted earlier the incentives at work here may variously include: (again) neoliberal, individualist political values; the power and lobbying efforts of TNCs in sectors such as food, soft drink or alcohol; and the influence of the medical profession or the media on health policy (Baum and Fisher 2014; Tesh 1988).

Conclusion

In this chapter we have provided an overview of contemporary evidence and understanding of biological, psychological, behavioural, social, economic, and environmental determinants of health. Identifying particular categories

of determinants can be very useful for analysis and research. Research focused on isolating and understanding the effects of particular factors on the health of individuals or populations has contributed to rich and detailed body of evidence on determinants of health and health inequities now available (Commission on the Social Determinants of Health 2008). Given this evidence, it is clear that governments and societies concerned with improving health cannot limit their attention to healthcare services, important as these may be. Neither can they reasonably believe that the adverse health impacts of (inter alia) tobacco, ultra-processed food, or alcohol are adequately understood as purely matters of individual 'lifestyle' choice. We have discussed the complexity of determinants and their interactions, and this might seem to suggest that determinants of health and health inequities are just too complex for governments to address successfully. However, this is not so: although the political challenges are no doubt significant, in principle what is required is to understand that addressing determinants of health to improve population health and reduce health inequities require multiple forms of action, at different scales, in different domains, and giving attention to different phases of the lifespan.

2.2

Politics of public health

Kaitlyn B. McBride and Linda Rosenstock

Introduction to the Politics of Public Health

The aim of public health is to improve and protect individuals and their communities, as well as promote evidence-based policy to drive decision-making across the larger health system. Researchers in academic institutions, government agencies, and the private sector provide the science to help policymakers make evidence-based health policy decisions, such as interventions to increase smoking cessation, or policies to improve access to preventive care services. Despite the proliferation of evidence-based policy research, and significant advances in both the prevention and treatment of disease, there has been consistent efforts to suppress and distort scientific research, as well as prevent the creation, implementation, and enforcement of laws to protect the public health of individuals and their communities.

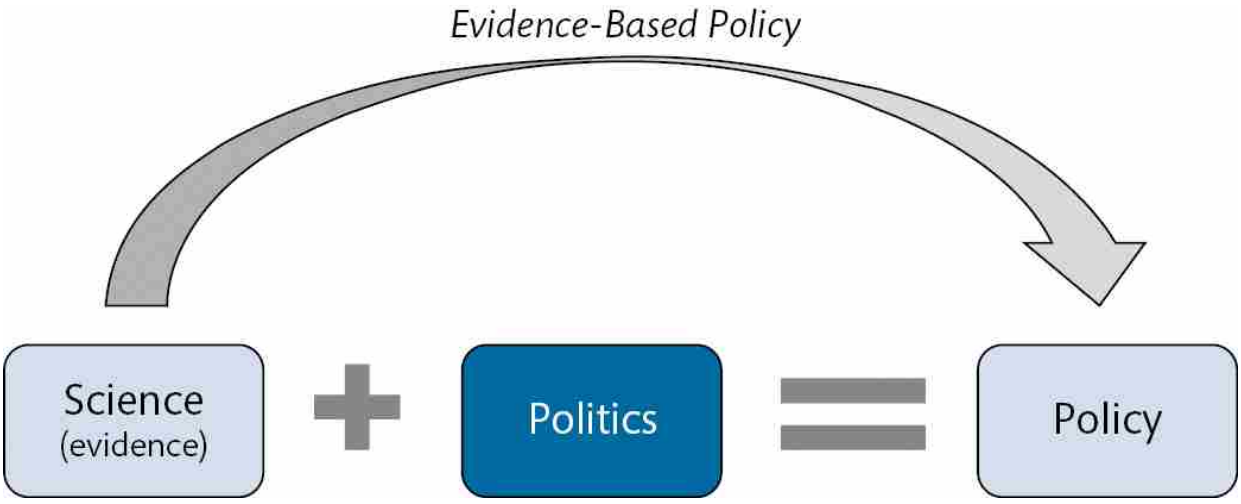

Fig. 2.2.1 A formula to guide the analysis of politics in the policy process.

Evaluating politics in the policy process can be reduced to the following components of the formula: Science + Politics = Policy (see Fig. 2.2.1). In an ideal world, science (or evidence) drives policy, with politics playing a minimal or enabling role. However, this formula recognizes that public health policy is not only decided based on science (or evidence), but science itself is increasingly vulnerable to the political process, and to attacks by a wide array of players (e.g. politicians, industry leaders, and interest groups) that have vested interests to undermine scientific evidence in order to thwart the actions that would credibly follow that knowledge. Put differently, politics are key—and can be systematically analysed—in advancing or thwarting evidence-based policy.

Unfortunately, the adoption of evidence-based research and practices is increasingly subjected to complex strategies—including economic manipulation, delays, harassment, and rhetoric—which weaken evidence-based policy (Rosenstock and Lee 2002; Rosenstock 2006). The politics in this arena involves significant trade-offs, and political leaders may elect to not support objective or scientific evidence, due to many factors, including biases (e.g. ideology and religion), fear of losing political capital (e.g. votes from constituents), loss of financial or political support from powerful organizations, or strong partisanship.

Framework for evaluating the politics of the health policy process

To examine the politics of the health policy process, our framework is a guide to evaluating how the role of politics influences the adoption of public health policy. To analyse this process, we will assess specific examples in a case-based approach, by expanding on the following domains:

Define the problem and evidence for policy interventions (The What)
Understand the roles and the players (The Who)
Understand motivations (The Why)
Understand strategies and tactics (The How)

The problem and the evidence (The What)

Defining the public health problem is the first step in 'the what'. For example, the problem might be that preventive care services are not sufficiently utilized. Once the problem has been identified, it is imperative that there is strong empirical evidence in support of a public health strategy to advance and improve the public health. For example, reducing an individual's out-of-pocket expenses (e.g. through added fees such as deductibles or co-pays) is an effective strategy for increasing preventive care utilization.

In this context, the collection of accurate data and objective, unbiased research is essential for establishing evidence-based policy (Choi, 2005). Additional components of high-quality scientific evidence include a sound analysis, comprehensive synthesis of findings, appropriate translation of results, and accessibility of information, either for policymakers, government officials, or for the general public (Choi 2005). An evidence-based approach in health policy can lead to both direct and indirect benefits, such as increased utilization of preventive health services, improved productivity among the workforce, and better quality of care for patients (Brownson et al., 2009).

The politics of the health policy process can best be analysed in focusing on steps 2–4 of the framework: The Who, The Why, and The How:

The players (The Who)

Policymaking is influenced by a myriad of players, including elected political leaders**,** public health officials, corporations, key interest groups, the media, and research institutions. In some settings, judicial review is key.

In general, policymaking is often driven by legislators and elected officials who shape the law. Understanding who the key players are, and how they work together, or in opposition to one another, is a key step in recognizing the role of politics in the policy process.

Motivations (The Why)

The motivation for pursuing a public health policy should ideally be driven by evidence-based public health research that results in policy that advances the public good. But health policy is also driven by economic, ideological, religious, and emotionally-held beliefs that are not always based on sound science. As such, motivations beyond those to increase the public good are key to understanding the role of vested interests—where one's interest, such as economic, may override the drive towards evidence-based policy.

For example, in many countries, elected leaders have prioritized ideology over sound empirical evidence in support of needle-exchange programmes (NEPs), a harm reduction strategy aimed to reduce the harms accompanied by risky health behaviours and illicit drug use. Arguments against needle-exchange programmes have been tied to moral and religious philosophies, which purport that harm reduction approaches, such as NEPs, condone amoral behaviour, and increase violence in communities. Despite the abundant evidence in support of NEPs in improving outcomes and decreasing disease burden, public officials continue to misrepresent and ignore scientific evidence for ideological purposes (Hwang 2007).

Laws restricting access to abortion are another example of public health policy driven by political, religious, and moral beliefs, rather than scientific evidence. Research has shown that laws restricting access to abortion and reproductive healthcare are harmful to women's health and well-being, and actually increase risk of injury or death; however, many countries have laws that criminalize abortion, as well as restrict access to reproductive health services, such as family planning (Berer 2017).

Strategies and tactics to undermine science and evidence-based policy (The How)

Strategies and tactics are key to advancing evidence-based policy, but all too often they are employed to thwarting policy that would protect the public

good. One key strategy is simply to attack the underlying science (or evidence), taking advantage of the distraction that claiming scientific uncertainty creates (Rosenstock and Lee 2002). A key example is climate change, where some question the mainstream of scientific opinion in order to undermine steps to mitigate climate-related adverse health effects. Economic manipulation is another tactic commonly used by politicians, interest groups, and corporations. For example, insufficient funding of regulatory and health agencies can limit the effectiveness of the policy apparatus. In addition, industry-sponsored research—especially in the US—is playing an increasingly large role as a source of funding, with a range of potential effects of altering the nature of the research itself to altering the dissemination of research results. In particular, the tobacco industry has used its financial ties to pressure health insurance companies to reduce consumer incentives to quit smoking (Shamasunder and Bero 2002). Due to these financial conflicts of interests, industry-sponsored research may lead to a suppression of study findings, prioritization of projects to produce economic gains, or biased interpretation of results by investigators (Okike et al. 2008).

Corporations, politicians, and vested interest groups also use delay and harassment tactics to forestall the release of sound science. Delay tactics includes funding of parallel studies (with the aim to confound the understanding of the original data), threats to sue, initiation of litigation, delay of hearing of the facts, and legislative barriers to prevent policies from being implemented. These vested interest groups have also been known to harass researchers and federal agencies to suppress scientific findings and prevent publications that support research in opposition to their economic interests (Rosenstock and Lee, 2002).

Conclusion

To be able to respond to attacks on science that are the underpinning of blocking evidence-based policy, the scientific community must increase its awareness of potential manipulation, distortion of empirical evidence, and conflicts of interest. This practice will hopefully encourage researchers and investigators to not only be vigilant about the potential consequences of undertaking industry-sponsored research but to understand their role in advocating for evidence-based policy.

Harm reduction strategies: needle-exchange programmes

An estimated 13 million people worldwide inject drugs—and 10% of HIV infections are attributed to injection drug use (IDU) (World Health Organization 2016). Use of contaminated needles is the primary mode of transmission of blood-borne viruses, such as HIV, hepatitis C (HCV), and hepatitis B (HBV), and is a significant contributor to worldwide morbidity and mortality (Degenhardt et al. 2017).

NEPs have shown to be an effective strategy to reduce transmission of infection among injection drug users. NEPs were first introduced in Amsterdam in the early 1980s by a group known as the Junkie Union. The primary purpose was to prevent the transmission of hepatitis B and HIV among injection drug users (Jarlais 2006). Studies later demonstrated a reduction in drug injection and HIV transmission among the programme's participants (O'Gurek and Kirchner 2010). NEPs were quickly adopted throughout Europe as a principal HIV prevention initiative and began to spread in US cities amidst the growing HIV/AIDS epidemic in the 1980s. During this period, NEPs gained support from several global institutions and non-governmental organizations, including the World Health Organization (WHO) and the Joint United Nations Programme on HIV/AIDS.

NEPs vary considerably in their design, services provided, programme policies, and daily operations (Fernandes et al. 2017). In addition to giving clean needles, the majority provide free testing for infectious disease (e.g. HIV and HCV), advice on safe injection and disposal practices, referrals to drug treatment programmes, such as opioid substitution therapy, and other supplies, including alcohol pads, and condoms.

NEPs are considered a harm reduction initiative aimed at mitigating risk among IDUs and reducing transmission of infectious disease (Clark and Fadus 2009). The term 'harm reduction' was first introduced in 1974 by the 20th WHO Expert Committee on Drug Dependence, referring to strategies aimed at reducing adverse consequences associated with drug use (Ball 2007). The concept and theoretical framework for the application of harm reduction strategies began initially with a defined focus on drug-related abuse; however, harm reduction policies have more recently been applied in response to broader public health issues ad not only drug-related harm, including alcohol abuse and sex trafficking (Myers et al. 2004).

From a public health perspective, harm reduction is a strategy that aims to reduce the harms that are accompanied by risky health behaviours. In the case of NEPs, these initiatives are a proven, practical public health approach to reduce injection-related infections, while not leading to an increase in injecting drug use (Witteveen and Schippers 2006). The science behind the effectiveness of NEPs has been well-established. Several studies have shown that these programmes lead to positive health outcomes among NEP participants, including reductions in needle sharing and injection frequency. Reviews of international evidence by the WHO and Institute of Medicine (IOM) have consistently found evidence in support of the effectiveness of NEPs in reducing the spread of HIV, and other risk behaviours, including syringe sharing among IDUs.

NEPs have been implemented in several countries, including Australia, Canada, Norway, Portugal, Spain, France, Italy, United Kingdom, China, and Malaysia. Despite the proliferation of empirical evidence and global support for NEPs– significant challenges remain in the global health response to the rapid spread of disease among IDUs. In 2016, of the 158 countries with reported injecting drug use, only 90 countries have implemented NEPs (Stone 2016).

The harm reduction strategy remains extremely controversial and underfunded in parts of the world, including Eastern Europe, Asia, and particularly in the United States. Opponents argue that NEPs lead to an increase of illicit drug use and perpetuate the cycle of addiction (Wodak and Cooney 2006). Others critique the philosophy of harm reduction, stating that harm reduction strategies condone immoral and illicit behaviour. These opponents support incarceration and punishment for IDUs, although there is no empirical evidence to suggest that this strategy leads to decreased use of illicit drugs, reduces crime, or prevents the spread of disease.

Case study Federal funding for needle-exchange programmes in the United States

In the United States, opposition to NEPs has historically been rooted in conservative and Republican ideology and moral philosophy, which purports that harm reduction initiatives such as NEPs, promote drug use, increase injection of illicit drugs, and lead to increased violence in communities. Although hundreds of needle-exchange programmes operate across the country, the United States has one of the lowest rates of needle-exchange availability and is one of the only countries to ban federal

funding for NEPs (Coleman, 2015). Consequently, ongoing programmes have limited resources to provide basic services, and must rely on private donations to operate. Lack of federal funding has also stalled widespread adoption of NEPs.

The debate over federal funding for NEPs has remained a steady battle between Republicans and Democrats since the introduction of NEPs in the 1980s. In 1988, during the height of the HIV epidemic in the United States, a federal funding ban for NEPs was put in place by Congress, which could only be lifted if it was determined that NEPs were effective 'in reducing drug abuse and transmission of HIV infection' (US Code Title 42: The public health and welfare). This 1988 ban set the stage for decades of policy driven by politics, not science, and an ideological war against providing clean needles for IDUs (Weinmeyer, 2016). Since the introduction of the federal funding ban, efforts by Democratic leaders to finance NEPs with federal dollars were defeated by five presidential administrations, regardless of the growing body of scientific evidence in support of NEPs, and increases in in intravenous drug use accompanied by a rise in transmission of HIV and HCV through shared needles (Mathers et al. 2013).

Fear tactics

In the United States the sharing of needles is due to fear of arrest for needle possession or violation of state laws and ordinances (Vlahov and Junge 1998).

Some law enforcement authorities resorted to scare tactics to demonstrate their opposition to needle exchanges. Officers threatened patrons at local NEPs and IDUs were afraid of being arrested if found exchanging old syringes for new ones. Other law enforcement associations lobbied against any legislation that would protect IDUs against the possession of illicit syringes (Cohen, 2003; Beletsky et al. 2011).

Attacks on science

Conservative interest groups and policy organizations have continued to oppose harm reduction policies with arguments tied to symbolism and moral philosophy. For example, the Drug Free America Foundation is a well-known group particularly adamant against harm reduction initiatives, including NEPs. They framed their arguments on the notion that needle exchanges promote drug use and enable drug users (Drug Free America Foundation, 2020). Other conservative groups also propagated the perception that injection drug users were not as important or worth saving as other members of society (Brownstein, 2016).

Opponents of NEPs also reference and misinterpret studies to show the failures by NEPs to curb drug use, even though subsequent research always upheld the views of the scientific community (Drug Policy Alliance, 2012). One study conducted in Montreal was repeatedly mentioned since it indicated that NEPs increased HIV transmission rates. However, the authors later claimed that the participants were not a representative population, and a large majority had a higher risk of infection (O'Gurek and Kirchner 2010). Despite the negation, Republicans, and opposition groups used these studies to add greater legitimacy to their support of the federal ban.

Policy window for federal funding

Republican leaders avoided addressing the growing public health crisis or legislation associated with NEPs, until the epidemic hit in their own states among their own constituents. At this time, the United States was experiencing rapidly increasing addiction rates, accompanied by a surge in HCV and HIV infections, predominantly affecting the Midwestern and Southern states, especially Kentucky, Indiana, and Tennessee (Zibbell et al. 2015). These states also had the strictest laws against NEPs and prevention initiatives like HIV testing.

In early 2015, Scott County, a region in southeastern Indiana, had a massive outbreak of HIV infections linked to IDUs injecting prescription opioids (Conrad et al. 2015). Republican Governor

Mike Pence authorized a needle-exchange programme to stall the HIV outbreak, effectively overriding state laws that prohibit syringe programmes (Rich and Adashi 2015). During the same period, Kentucky saw a surge of hepatitis C infections in nearly 54 counties, also linked to IDU. With this latest outbreak, a window of opportunity opened for bipartisan legislation to end the decades long ban for NEPs. Two Republican leaders from Kentucky ensured language was included in the 2016 legislative spending bill to end the federal funding ban. Some members of Congress who had historically supported the ban, finally acknowledged that legislation was necessary to counter the growing public health crisis.

At first glance, it finally looked like a win for advocates and Democrats, however, the federal funding ban was not *fully* repealed. The bill currently includes language that will allow state and public health departments to use federal funds for NEPs, 'as long as the federal funds do not purchase the syringes' (Consolidated Appropriations Act 2016). Federal funds for NEPs can also only be used in areas with high rates of IDU, deemed eligible by the Centers for Disease Control and Prevention (CDC). Furthermore, the bill does not guarantee any more federal funds for NEPs, just a shift in funding.

Although though it took nearly three decades, the lifting of the ban in 2016 signals a shift in conservative politics towards implementing evidence-based preventive harm reduction policies.

The politics of women's reproductive health

Tremendous improvements globally have been documented in recent decades in women's reproductive health and related quality of care. From 1990 to 2015, maternal mortality dropped by about 44% worldwide (Alkema et al. 2016). Despite this progress, significant challenges remain in meeting the reproductive healthcare needs for women and girls. Access to family planning services, including contraception, is still significantly limited in many low- and middle-income countries, and those countries bear a disproportionate burden of maternal mortality and morbidity. Recent estimates indicate that nearly 810 women die every day from preventable causes associated with pregnancy and childbirth, such as high blood pressure, delivery complications, and unsafe abortions; and approximately 94% of maternal deaths worldwide occur in low and-middle income countries (World Health Organization 2019).

The accessibility and availability of quality family planning and reproductive health services, including safe abortion services and effective contraceptive methods, are key components to preventing maternal mortality and morbidity (Filippi et al. 2016). A recent study of 172 countries found contraceptive use in one year avoided approximately 272,040 maternal deaths (a 44% reduction), and would have prevented an additional 102,000 deaths (29% reduction) if the unmet need for contraceptives been addressed (Ahmed et al. 2012). Research has further shown that the use of effective

family planning and contraception methods decreases the number of unintended pregnancies, including among adolescent girls, results in significantly fewer unsafe abortions, and is also an effective approach to reducing costs associated with HIV/AIDS (World Health Organization 2018a).

Although access to effective sexual and reproductive healthcare has been shown to reduce national and global rates of maternal mortality, as well as pregnancy-related health risks, many countries fail to provide these services, and women face significant barriers to accessing them. It is estimated that about 225 million women of reproductive age in developing countries lack access to birth control and effective family planning services primarily due to cultural or religious opposition, poor access to quality health services, or restrictive laws and regulations (Sedgh et al. 2016).

The US, because of its own domestic policy debates, has played a disproportionate role in curtailing access to and information about safe abortions globally. One policy, created by executive mandate of the US President without congressional approval, and that affects countless women worldwide, is the 'Mexico City Policy', also known as the Global Gag Rule. This rule initially implemented under the Reagan administration in 1984, curtailed US Agency for International Development family planning funds going directly or indirectly to non-US-based non-governmental organizations (NGOs) (international or regional NGOs located outside the United States and local NGOs) that provided information efforts, or counselling about or access to safe and legal abortions (Crane and Dusenberry 2004). The Gag Rule policy established a dangerous precedent for curtailing women's rights for safe and effective sexual and reproductive healthcare worldwide—effects well beyond the intended restriction on provision of abortion information and services—and which has caused significant damage towards women's access to services.

Research on the impact of the Global Gag Rule found evidence that the Mexico City Policy, because of its overall effect on the NGO community including limiting access to family planning services, is associated with increases in abortion rates in several sub-Saharan African countries. One study found that abortion rates rose dramatically in countries with high exposure to the Gag Rule (namely, those most vulnerable to the funding restrictions) compared to those with low exposure (see Fig. 2.2.2) (Bendavid et al. 2011).

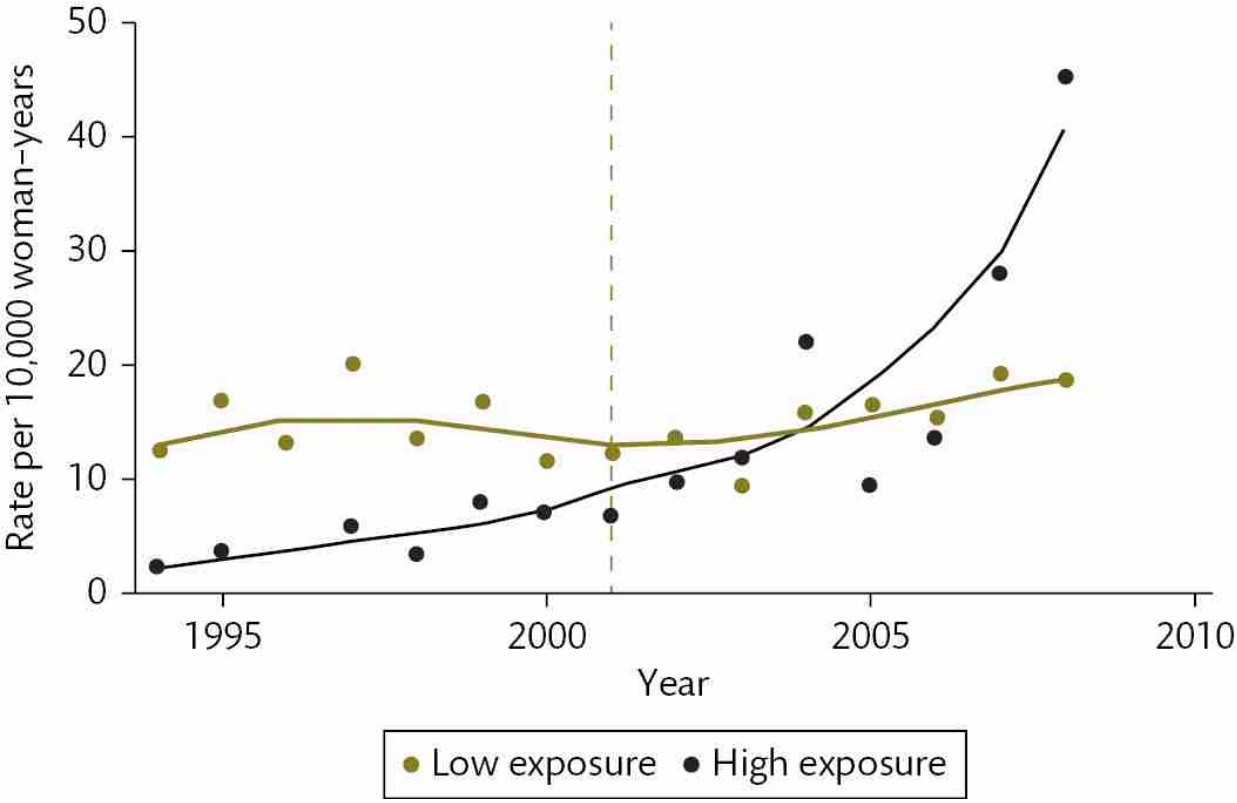

Fig. 2.2.2 Abortion rates in 20 sub-Saharan African countries, by exposure to Gag Rule, 1994–2008. Reprinted from Bendavid, E., Avila P., and Miller, G. United States aid policy and induced abortion in sub-Saharan Africa. *Bull World Health Organ*. 2011. Vol. 89. Number 12. doi: 10.2471/BLT.11.091660. Figure used under Creative Commons Attribution 3.0 IGO licence (CC BY 3.0 IGO).

The Gag Rule has historically been supported by Republican Presidents (and removed by Democratic ones), reflective of highly partisan views (in part driven by moral and religious ideologies) of women's reproductive rights in the United States. The policy was recently reinstated by President Trump in January 2017 (Congressional Budget Office 2017), and as with many such policies in this administration, broadened even further than previous norms. Currently, the scope of the Gag Rule goes beyond US AID family planning funding (about $700 Million USD per annum) to include most US Government global health funding (about $9 Billion USD per annum). The consequences of this broadly expanded Global Gag Rule are as yet unmeasured, but are likely to include far more negative consequences than during previous Republican administrations.

Case study Reproductive health rights for women in the US

Despite formidable odds, President Barack Obama signed the Patient Protection and Affordable Care Act (ACA) on 23 March 2010. This historic legislation also marked a new era of partisanship in Washington as well as the beginning of endless Republican congressional efforts to repeal the law. Prior to the implementation of the ACA, access to healthcare and preventive services was a significant challenge for millions of Americans. Following the law's passage, millions more gained health insurance, along with coverage for preventive care services without out-of-pocket costs to the consumer. The original legislation did not include key preventive service coverage for women. This was addressed by an amendment to the ACA that resulted in the formation of a review process led by the Institute of Medicine (now, National Academy of Medicine) to identify gaps in coverage for women that should be included as benefits (Council 2011). After a contentious roll out of these added benefits, the small but vocal opposition was largely focused on the decision to include the full range of US Food and Drug Administration (FDA) approved contraceptives. Soon coined by opponents as the 'contraception mandate' (no more a mandate than any of the other listed evidence-based preventive measures similarly offered without cost-sharing, such as screening colonoscopy or mammography), the inclusion of family planning services as an insurance benefit has been strongly opposed by most Republicans, some employers, and many social conservative and religious organizations.

The science

There is significant research to indicate that expanded family planning coverage has largely benefited women and teens of reproductive age in the United States. Following the implementation of the policy of expanded insurance coverage, the number of US abortions decreased by more than 132,000 between 2011 and 2014 (the abortion rate fell to 14.6 abortions for every 1,000 women between the ages of 15–44, a 14% drop since 2011) (Dreweke 2017). In addition to the health benefits of reductions in unintended pregnancies and concomitant abortions, there are other health benefits including decreased maternal morbidity and likely benefits to both mother and child of more optimal birth spacing (Cleland et al. 2012). Contraception use also confers several economic benefits; for example, prior to the ACA's mandate, out-of-pocket expenses for contraceptives was a large portion of women's medical expenditures, amounting to about 21 percent of their total out-of-pocket healthcare spending (Taylor and Mhatre, 2017). Recent evidence indicates that women saved $1.4 billion in out-of-pocket payments in 2013 resulting from the ACA's inclusion of family planning as a covered preventive service (Polsky 2015).

The players (The Who)

The ACA family planning benefits expansion drew a broad array of opponents despite broad support among the population. Opponents include religious organizations (notably, Catholic-affiliated organizations and employers), antiabortion groups, and the majority of Republican lawmakers. Reproductive health access opposition was driven by several components, based on religious, ideological, and political grounds.

Those in support of greater access to contraception and reproductive health rights for women in the United States tend to include most Democrats along with women's health advocacy groups, and pro-choice organizations. Universal access to contraception in the United States is also largely supported by key professional and academic organizations, including the National Academy of Medicine, the American Academy of Pediatrics, the American Academy of Family Physicians, the American College of Obstetricians and Gynecologists, and the American Public Health Association.

United States Supreme Court and the ‘contraception mandate’

The Supreme Court has played a significant role in the contraception debate in the United States In 2012, Hobby Lobby, an arts and crafts company founded and owned by the Evangelical Christian Green family, filed a lawsuit against the United States over the new regulation requiring health insurance be provided to cover the full range of contraception methods, citing objections to the inclusion of emergency contraception (often known as Plan B or the ‘morning after’ pill) and intrauterine devices (IUDs). In the Supreme Court Case (Burwell vs. Hobby Lobby, decided in July of 2014), a divided court 5–4 struck down the ‘contraception mandate’ for family-owned businesses, based on alleged violation of the federal Religious Freedom Restoration Act (Luchenister 2015). This was the first time in US history that the court ruled that a private corporation can claim to have religious beliefs and deny employees a federal benefit.

Attacks on science

Several tactics were used by opponents to undermine the science behind the family planning rule; challengers attempted to weaken support for the evidence-based policy with conservative rhetoric and delay tactics through litigation, motivated by ideology and partisan politics. For example, religious organizations and social conservatives, as well as the owners of the Hobby Lobby, erroneously equated emergency contraception drugs with abortion (Carroll 2014). Although this was unsupported by any empirical evidence, religious leaders and conservative lawmakers continue to spread the notion that certain family planning methods and contraception options, such as IUDs, are a form of abortion and thus constitute a violation of faith; this rhetoric was used to garner support from their constituent-base and antiabortion activist groups.

The future of women’s reproductive health rights

Although the majority of the American public support mandated coverage of birth control in health plans, the law’s family planning inclusion as a preventive benefit remains a politically polarizing and controversial topic, primarily along partisan lines (Moniz et al. 2014). Republican party leaders and lawmakers are increasingly gaining support to restrict reproductive rights for women; Republican-leaning states have also slowly eroded women’s access to safe abortions and reproductive health rights in recent years; between 2011 and 2016 states enacted nearly 334 abortion restrictions (Nash 2016). There are now new efforts to reduce reproductive health funding and access for women under President Trump, and conservative lawmakers continue to attack the ACA’s contraception coverage and funding for women’s health. Although not a problem unique to the United States, as other countries are in general broadening access to such services, the United States is experiencing a serious erosion of women’s sexual health and reproductive rights.

Evidence-based policy challenged by politics: income inequality and health

Despite recent increases in overall economic growth, global income and wealth inequality have been rising steadily since 1980; for example, the wealthiest 1% have increased their total wealth twice as much as the poorest 50% of the world’s population (Alvaredo et al. 2018). In some countries,

including India, China, and the United States, growth in income inequality between 1980 and 2016 has increased exponentially, as a result of various factors- including educational inequalities, tax policies, and deregulation. Conversely, the rise in inequality has grown only moderately across continental Europe, primarily attributed to social, educational, and tax-related policies that favoured the middle- and lower-classes (Alvaredo et al. 2018).

There are several methods for assessing the level of inequality in society. One widely accepted global measure is the GINI index, which is used for evaluating the level of income inequality within and across different countries (De Maio 2007); the index is a statistical measure to represent income (or wealth) distribution in a country. A coefficient of 1 (or 100%) represents maximum inequality (e.g. all wealth in one individual), while perfect equality is represented by a coefficient of 0.

Using the GINI index from World Bank estimates, South Africa and Zambia, as shown in Table 2.2.1, are among the most unequal countries in terms of income distribution—while Ukraine, Sweden, and Norway are among the most equal nations in the world. China and the United States have similar levels of income inequality and fall in the middle of country rankings in terms of inequality (World Bank 2018).

Table 2.2.1 Global income inequality using the GINI Index

Country	GINI %
South Africa	63.0

Norway	27.5
Ukraine	25.0

Lower % reflects less inequality.

Source: data from World Bank Development Research groups GINI Index estimates (2012–2016).

Substantial evidence shows that poverty in and of itself is a significant risk factor for poor health. In recent decades, evidence is accumulating that shows income and wealth inequality, in addition to poverty *per se*, are independent drivers of mortality and morbidity (Pickett and Wilkinson 2015; Williams and Rosenstock 2015). The additional role of another socioeconomic status indicator, namely, wealth and income inequality, is not surprising in the context of a Social Determinants of Health Framework, which posits a wide array of factors beyond biology and access to healthcare that have outsized influence on health throughout the life cycle (Friedman and Starfield 2003).

A WHO Commission employed this framework to elucidate the main pathways through which social, economic, and political mechanisms influence socioeconomic status and social positions, inequities in education and household wealth, and how this shapes health status and vulnerabilities to specific health conditions. Social position and socioeconomic status are also influenced by income, since poor health status may affect employment, or other opportunities in various social and economic structures (Solar and Irwin 2010).

A substantial body of literature demonstrates that from a population level-perspective, economic and social deprivation have a direct link on incidence of disease. Several studies have evaluated the relationship between low socioeconomic status and increased risk of morbidity and mortality (Brown et al. 2004; Bosworth, 2018). This evidence is reflected in life expectancy across countries- income inequality (as measured by the GINI coefficient) is one factor in explaining differences in life expectancy. Individuals living in nations with lower levels of inequality have been shown to have longer life expectancies (Deaton 2003). In 2016, the average life expectancy in Sweden is 82.4 years (one of the most equal countries), the US average life expectancy is 78.5, and South Africa is 63.6 years (one of the most unequal countries) (World Health Organization 2015).

Evidence also shows that child and adolescent mortality is higher in countries with increased income inequality. One study found, using the GINI coefficient, that income inequality was positively associated with increased all-cause and communicable disease mortality in both males and females (Ward and Viner 2017). Additionally, researchers have also found evidence to suggest direct links between wealth inequities and mental health and overall psychological well-being; a recent review evaluating the association between income inequality and depression found that countries with larger gaps between the rich and poor have a higher incidence of mental illness (Patel et al. 2018).

In sum, the evidence supports that higher stress and depression, and higher rates of morbidity and mortality, occur among countries with significant income inequity. Evidence further indicates that greater income equality leads to slower economic growth, and leaves countries more vulnerable to political corruption.

Case study The politics of US income inequality in a global context

By several measures, income inequality in the United States has risen since 1980. The wealth gap in the United States has also increased steadily in the past few decades, and is currently the highest in the country's history. As of 2016, the wealthiest 1% of Americans own nearly 40% of the nation's wealth (Wolff 2017).

The relation between income inequality in select developed countries and an index of social, economic and health outcomes (including mental illness, obesity, imprisonment, education, and social mobility) is shown in Figure 2.2.3. There is a clear correlation between rising inequality and poor outcome, with the United States an outlier in both measures.

The US is the only advanced economy without universal healthcare; the country also performs poorly on several indicators, compared to other nations, including maternal mortality, and life

expectancy. Among the 37 countries in the Organization for Economic Cooperation and Development (OECD), the US ranks 28th in life expectancy at birth (OECD 2020).

In addition to the growing gap between rich and poor, the US is also experiencing a dramatic reduction in the size and standing of the middle class. Middle-class Americans have experienced a much greater decline compared to other advanced economies across continental Europe (Kochhar 2017). Research also shows growing income disparities by race and ethnic groups—the racial and ethnic disparity in wealth holdings widened considerably between 2007 and 2016 (Wolff 2017).

The political context of rising inequality in the US

Although inequality has been rising for decades in the US among both Republican and Democratic administrations, there is a clear partisan divide about perception of the issue and responses to it. Republicans are more

likely to associate a person's financial standing to his/her own hard work, and are also less likely to favour taxes for the wealthy that mitigate inequality, or advocate for policies to raise the minimum wage; however, Democratic counterparts tend to argue that social and economic determinants, and institutional factors embedded in society, such as structural racism, are the primary drivers of poverty and inequality. Democrats also favour policies aimed to support lower and middle-class families (Smith 2017).

Partisan divide over solutions for inequality

This partisan divide towards solutions to address the widening income gap are ever more apparent in two recent legislative bills: The Patient Protection and ACA, passed in 2010, and the recent Republican Tax Bill of 2017.

The ACA was passed by President Obama and Democrats in 2010. This remarkable legislative achievement—the first major health and social legislation in decades—had a significant impact on inequality for the nation. The goal of the ACA was to make health insurance more affordable for low- and moderate-income families. Following the law's implementation, nearly 20 million more Americans gained health insurance, reducing the uninsured rate to the lowest level on record (Cohen and Martinez 2016). It also reduced inequality (increased high earning taxes) and redistributed benefits, made many more families financially secure (blunting for lower-income shocks of healthcare cost), and lowered the federal deficit. A recent report found healthcare access for people in lower socioeconomic strata improved following ACA implementation and reduced disparities, with the gap in insurance coverage between higher- and lower-income households falling (Griffith et al. 2017).

In contrast, President Trump and Republican lawmakers passed the 'Tax Cuts and Job Act of 2017', the largest tax reform in decades, which effectively redistributed wealth to leading corporations and the wealthiest Americans. President Trump and Republicans claimed several victories in passing this bill: lowered the individual top tax to 37% (from 39.5%), lowered corporate tax rate to 21% from 35%, and repealed the ACA individual mandate (the mandate not only assured through penalties broad participation and hence stabilization in the insurance markets, but also banned health insurance companies from discriminating against individuals

with pre-existing conditions). Although the 2017 tax legislation does reduce taxes, if only slightly, across all income groups, the bill will continue to increase income inequality; higher income households will receive larger average tax cuts as a percentage of after-tax income; the biggest cuts as a share of income will go to taxpayers in the 95th to 99th percentiles of the income distribution, and the wealthiest will receive the largest cuts of all (Tax Policy Center 2018).

Solutions to address global inequality

Substantial evidence indicates income inequality across regions and countries is driven by a multitude of social and political factors—as well as disparities in educational and economic opportunities. The downstream effects of increasing inequity not only harm individuals and their surrounding communities, as evidenced by worse health outcomes, increased crime rates and political instability, but impede investments in education and training programmes for future generations.

To address the rapidly increasing structural inequities, the WHO recently identified several evidence-based policy options, with a particular focus to improve social determinants of health within the four following areas: childhood education and development, fair employment, social protection (e.g. cash transfers), and living and environmental conditions (e.g. housing affordability, legal protections) (Saunders et al. 2017). The various mechanisms to address systematic inequities in education, health, food security, etc., integrate several policy frameworks; however the underlying construct through which equity can be obtained is through short- and long-term investments in social determinants of health. With a more explicit policy focus to address upstream factors, such as economic stability and physical environment, regions and countries will see improvements in long-term economic growth, as well as improvements in health outcomes for the population (Nichols and Taylor 2018).

Conclusion

Decision makers can mitigate threats to science (the public health evidence-base) by recognizing that broad-based support and public education are key to enacting and enforcing effective health policies, on both a domestic and

global scale. The mainstream media as a purveyor of trusted information to the public needs to be protected from politically motivated attacks (e.g. in both the US and globally, the rhetoric in some quarters about false vaccine-related threats to health are aided when the public no longer knows who to trust).

The role of science in public health today is critical for evidence-based policy, and crucial for improving public health worldwide. Advancement of policy based on sound science will continue to be necessary to combat growing global public health crises and respond effectively to new public health threats. Understanding the players, their motivations, and tactics used, is fundamental to analysing the role of politics in the process.

Poverty, justice, and health

Ronald Labonté, Fran Baum, and David Sanders

Introduction to poverty, justice, and health

> Poverty has to be understood not just as a disadvantaged and insecure economic *condition*, but also as a shameful and corrosive social *relation*. (p. 7, emphasis in original)
>
> Lister, R., *Poverty*, Polity Press, Copyright © 2004.

Poverty has long been a concern in public health. Not only do people living in poor circumstances generally suffer higher burdens of disease, but during periods of infectious epidemics or pandemics they are perceived as posing a risk to others as well. Studies even suggest that high poverty and disease rates together can contribute to social unrest and 'failed' (or failing) states (Cheek 2001; Hotez 2002; Singer 2002; Peterson and Shellman 2006). Apart from these more 'public' (or population) health risks, the persistence of poverty has also led many public health theorists and practitioners to ask why poverty continues to exist in times of great global wealth, and to argue that a socially just society would seek to eliminate poverty. The reasons for the persistence of poverty lie in how societies' economic and political systems allocate the opportunities and resources people need to be 'non-poor' and healthy, or intervene to reduce inequities (avoidable inequalities) in their access to services and resources. Thus, any discussion of poverty, and of its impacts on health, unavoidably intersects with understanding how inequalities arise in the distribution of income and wealth, and of the material and psychosocial resources these socioeconomic privileges accord. As the British economist-cum-philosopher, Adam Smith, known best for his writings extolling the virtues of free markets, noted:

> Wherever there is great property, there is great inequality. For one very rich man, there must be at least five hundred poor, and the affluence of the few supposes the indigence of the many. (Smith 1776, p. 419)

To further our understanding we need to answer the question of what poverty is exactly? How is it affecting health, and ill health affecting poverty? And what theories or practices of justice should guide public health interventions based on poverty's persisting health risks? These three questions form the basis of the chapter that follows.

What is poverty?

At first glance, it may seem simple to define poverty: the inability of people to provide for the basic necessities of life. But there are actually many forms of poverty, all of them important to public health and to public policy; and the concept of poverty itself is 'highly contested' (Alcock 1993). Its contestation is not simply theoretical (what does it mean?) or empirical (how do we measure it?) but also political, since it is the same sociopolitical structures and economic arrangements that give rise to both poverty and affluence.

Absolute poverty

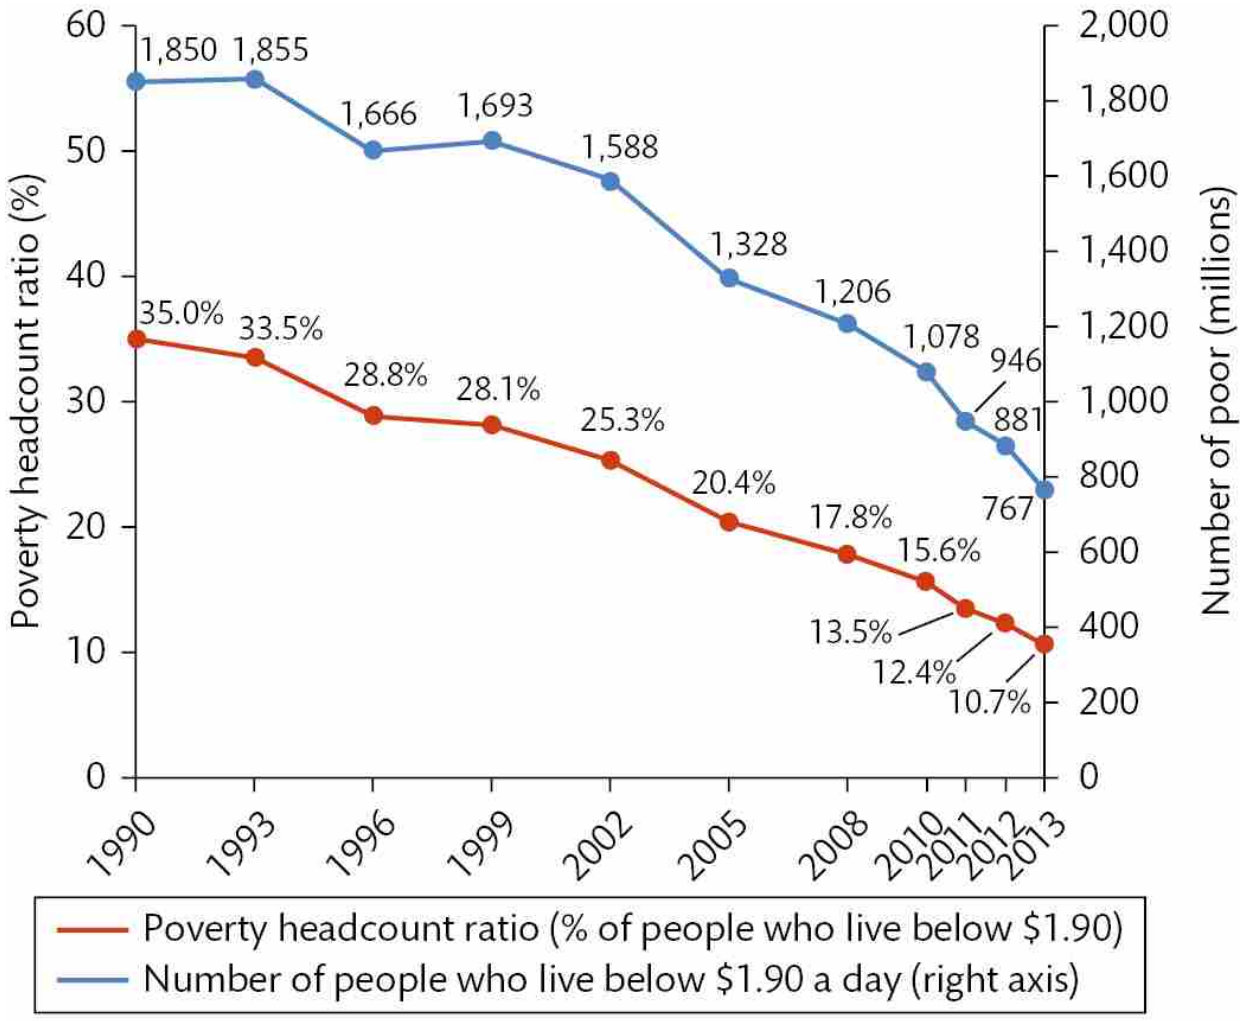
There are people in the world so hungry, that God cannot appear to them except in the form of bread.

Mahatma Gandhi

Absolute poverty is foundational to an understanding of the concept, and is commonly considered to be the lack of a minimum income necessary for simple survival based upon the price of a basket of 'essential' goods and services (Masters and Wickstrom 2006; Saunders et al. 2008). The World Bank standardized poverty measures globally through its 'dollar-a-day' poverty rate. The dollar-a-day level, close to the national poverty line in India, was subsequently raised to $1.25/day and then revised upwards once again to $1.90/day, which remains the World Bank's headline measure of 'extreme' or absolute poverty (Ferreira and Sanchez 2017). Extreme poverty, or what is now referred to as the 'lower bound' rate (Ravallion and Chen 2017), describes subsistence consumption at a level that is minimally life-supporting and 'exceptionally frugal . . . even by the standards of the world's poorest countries' (Chen and Ravallion 2012, p. 1). It remains associated with comparatively low life expectancies and high infant and maternal

mortality rates. (We discuss the relationship between poverty and health later in this chapter.)

Global poverty at the $1.90/day extreme level has fallen consistently since the baseline year of 1990, both proportionately (the ‘headcount index’) and in absolute numbers (Fig. 2.3.1) (World Bank 2016), often attributed to globalization-associated economic growth (Santarelli and Figini 2002; World Bank 2002). There are important regional variations. Poverty rates and absolute numbers fell most dramatically in East Asia and China. Poverty rates and absolute numbers rose in Latin America and the Caribbean during the 1980s and 1990s—the ‘lost decades’ that many attribute to structural adjustment programmes imposed by the World Bank and International Monetary Fund (Grindle 1996)—before beginning to fall in the 2000s. The recent decline in poverty in this region is a result of economic growth combined with redistributive social policies and programmes (Birdsall et al. 2011). Poverty rates in sub-Saharan Africa fell only slightly over this 30-year period, and only since the early 2000s, and failed completely to keep pace with population growth with the number of people living in extreme poverty rising from 276 million in 1990, to 389 million in 2013 (latest year available) (World Bank 2016).



Source: Latest estimates based on 2013 data using PovcalNet (online analysis tool), World Bank, Washington, DC, http://iresearch.worldbank.org/PovcalNet/.
Note: Poverty is measured using the US$1.90-a-day 2011 PPP poverty line.

Fig. 2.3.1 Trends in the Global Poverty Headcount Ratio and the Number of the Global Poor, 1990–2013.

Reprinted from World Bank. 2016. Poverty and Shared Prosperity 2016: Taking on Inequality. Washington, DC: World Bank. doi:10.1596/978-1-4648-0958-3. License: Creative Commons Attribution CC BY 3.0 IGO.

These data mean that the not very ambitious Millennium Development Goal of halving the number of people living in extreme poverty between 1990 and 2015 has been achieved. Of comparative significance is that the value of the global economy more than quadrupled during this same time period—from US $18 trillion in 1980 (De Long 1998) to US $80 trillion in

2011 (Central Intelligence Agency 2013), indicative that very little 'trickle down' of the benefits of that growth reached the 'bottom billion' (Collier 2007). Neither does halving these rates say anything of the adequacy of the poverty lines themselves, to which other analysts have responded with estimates of an 'ethical poverty line'.

The ethical poverty line

The ethical poverty line was first established by working backwards from countries with an average life expectancy at birth of 74 years (considered an ethical minimum) to the average level of consumption associated with such a life expectancy (around $3/day when the study was first made) (Edward 2006). More recent estimates of the income (measured as consumption) required for this still modest outcome (since many in high-income countries can expect to live well past 80 or even 90 years by 2030 (Kontis et al. 2017)) range between US$5/day and US$7.40/day (Hickel 2016).

The 2015 Sustainable Development Goals (SDGs) established a slightly more ambitious target than the MDGs: eliminate extreme poverty worldwide by 2030. But what of poverty at levels that approach the 'ethical' minimum? Using the US$5/day level (the minimum the United Nations Conference on Trade and Development in 2013 considered to qualify as a poverty line, and below which over 4.3 billion people presently live), and based on current poverty reduction trends, when 2030 dawns: 15% in Latin America and the Caribbean would still be poor, rising to 30% in East Asia and the Pacific, 50% in the Middle East and North Africa, and an astounding 90% in South Asia and sub-Saharan Africa (United Nations Conference on Trade and Development 2018). At the current rate by which the global economy has been reducing poverty, it would take 200 years to eliminate poverty at the US$5/day level, and over 300 years at the US$7.40/day level (Woodward and Simms 2015). Even if these more appropriate absolute poverty targets were eventually achieved, doing so under the current norms of economic growth would almost certainly destroy the ecological resources required for life long before achieving this effect.

Finally, the World Bank's estimates of people living in absolute poverty are generally based on what people report consuming. Since many of the world's poor consume healthcare for which they have to pay, this can result in medical poverty, when catastrophic illness forces people to sell their

assets and exhaust their savings to pay for treatment. These people may lift themselves out of 'consumption' poverty (since they are consuming healthcare at a high level) but leave themselves in income poverty (since they no longer have money for other goods or services). In 2005, the World Health Organization (WHO) estimated that:

> Each year 100 million people slide into poverty as a result of medical care payments. Another 150 million people are forced to spend nearly half their incomes on medical expenses. That is because in many countries people have no access to social health protection — affordable health insurance or government-funded health services. (WHO 2005).

This estimate is still considered to be largely accurate (Aizenman 2017), although there is some evidence that the number may be declining slightly (Wagstaff et al. 2018). Recognizing the seriousness of medical poverty, in December 2012, the United Nations General Assembly passed a resolution calling on Member States to develop universal health coverage systems to prevent significant payments at the point of delivery and to pool risks to avoid catastrophic healthcare spending and impoverishment (United Nations General Assembly 2012). This 2012 resolution has since become embodied in the 2015 SDG 3 (Good Health and Wellbeing), and its Target 3.8:

> Achieve universal health coverage, including financial risk protection, access to quality essential healthcare services and access to safe, effective, quality, and affordable essential medicines and vaccines for all. Achieving universal health coverage (UHC) has also become a platform initiative of the WHO.

Absolute (extreme) poverty informs public health by way of a presumption that people living at or below such poverty lines lack access to sufficient material resources to develop or maintain their health. This level of poverty represents a form more commonly associated with poor groups in low-income and middle-income countries than with poor groups in high-income countries. This poverty concept nonetheless applies to high-income countries where some households live in 'deep poverty', where income levels are 75% or less of nationally established poverty lines and are considered inadequate to meet even basic needs of food, shelter, and clothing (Beiser et al. 2002). Conservative think-tanks in high-income countries have sometimes argued that absolute poverty, which is indifferent to measures of income or wealth distribution, should be the only policy concern. Not all agree. Apart from growth-related poverty reduction being much less under conditions of high-income inequality (Bourguignon 2004), most of the

world's absolute poor now live in middle-income countries such as India and China, making governance, taxation, and redistribution of paramount importance in reducing levels of absolute poverty (Sumner 2010).

Recognizing that there is no longer a bifurcated world of 'developed' and 'developing' countries, the World Bank has organized nations into four groups based on their average per capita incomes (adjusted for purchasing power parity). Building upon a study that averaged national poverty line rates for countries at different development levels for which data were available (Jolliffe and Beer Prydz 2016), the World Bank defined poverty as $1.90/day for 33 low-income countries, $3.20/day for 32 lower-middle-income countries, $5.50/day for 32 upper-middle-income countries, and $21.70/day for 29 high-income countries (Ferreira and Sanchez 2017). In 2017, it also created what it called a poverty level 'upper bound', 'a schedule of weakly relative lines that rise with the … national poverty lines' (Ravallion and Chen 2017, p. 8) and adjusted to account for the effects of the 'very high incomes' of the top 1% (and even the top 0.1% and 0.01%) which has captured much of the world's income gains since 1980 (Alvaredo et al. 2018). Using the upper bound measure, world poverty since 1990 declined very little, and actually continued to increase (in actual numbers of poor people) in Latin America, the Middle East and North Africa, South Asia, and sub-Saharan Africa (Ravallion and Chen 2017).

Relative poverty

> Poverty means going short materially, socially and emotionally. It means spending less on food, on heating and on clothing than someone on an average income—above all, poverty takes away the tools to build the blocks for the future. It steals away the opportunity to have a life unmarked by sickness, a decent education, a secure home. (p. 3)
>
> Reproduced from Oppenheim C. and Harker L., Poverty: the facts, Child Poverty Action Group, London, UK, Copyright © 1990.

The World Bank's use of 'weakly relative lines' of poverty introduces the concept of relative poverty, and the idea that it is not enough simply to be able to meet the material necessities of life. One is poor if one lacks the resources required to engage in some meaningful ways in society and its sundry activities (social, economic, political, cultural, and recreational). That is, relative poverty is concerned with living standards—which vary by place and over time, but which convey the notion of comparatively full social functioning. This concept of relative poverty as the inability to function

socially to some normative standard can be traced in Western thought as far back as Aristotle (Sen 2000). Peter Townsend was one of the first of the recent theorists to criticize the policy use of absolute poverty.

He, and others since, argued for a concept of ‘relative poverty’ based less on minimal needs for survival and more on needs conditioned by societal expectations—that is, on what people require to participate fully in society (Nunes 2008; Eurostat 2010). This concept of relative poverty is actually reasonably old even in liberal economic thought, having been famously proposed by Adam Smith in his statement that ‘a creditable day-labourer would be ashamed to appear in public without a linen shirt, the want of which would be supposed to denote that disgraceful degree of poverty’ (Labonté et al. 2012, p. 15).

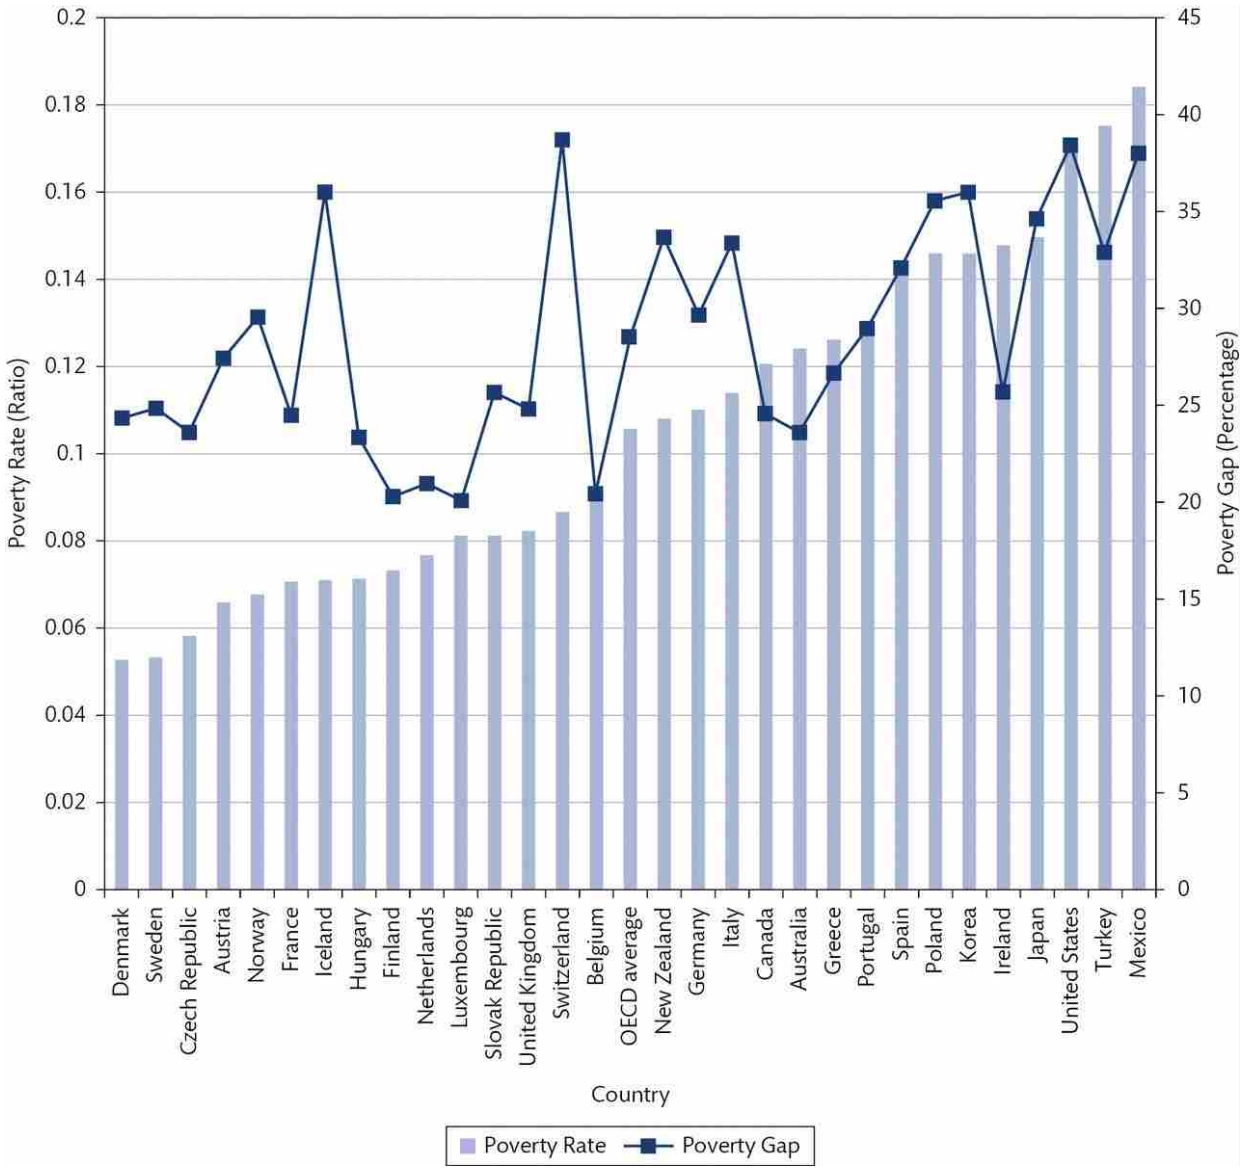


Fig. 2.3.2 Poverty rate and poverty gap, selected OECD countries.

Adapted with permission from Organisation for Economic Co-operation and Development (PECD), *OECD Factbook 2010: Economic, Environmental and Social Statistics*, OECD Publishing, p. 237, Copyright © 2010, DOI: 10.1787/factbook-2010-en.

As Martin Ravallion, the World Bank's expert on global poverty and lead analyst for the absolute measures discussed earlier, points out, this passage from Smith implies that 'certain socially-specific expenditures are essential for social inclusion, on top of basic needs for nutrition and physical survival' and that 'the way this idea is implemented in practice is to set a "relative poverty line" that is a constant proportion of average income for the country' (Ravallion 2011).

The more common relative poverty measure is having a net household income (one that takes into account government cash transfers and taxes, and that is adjusted for family size and often also for urban or rural location) that is below 50% of the country median. This measure is commonly used for comparative studies within or across high-income countries, i.e. those belonging to the Organisation for Economic Co-operation and Development (OECD). Figure 2.3.2 provides an example using OECD countries, which includes the 'poverty gap'—the median of how far below the relative poverty line a household falls and a measure of 'deep poverty' (OECD 2010). Figure 2.3.3 focuses on relative child poverty in economically advanced countries (UNICEF 2017) defined as living in a household with income level lower than 60% of the median. A relative concept of poverty informs public health by expanding the range of goods and services that members of a household should be able to access to experience, in Ravallion's terms, social inclusion, and the mental and physical health benefits such inclusion might garner. At the same time, the monetization of the concept (pegging it to a percentage of average or median income) has been criticized since it represents a form of poverty that will never disappear. As average or median incomes rise in a population, there will always be some who will fall below these cut-offs. It is possible for absolute poverty to fall within a country or region, while relative poverty rises; since the relative poverty cut-offs can be affected by disproportionate increases in income among a minority of the population, even if the material conditions of those at the bottom of the income gradient improve. As an earlier UNICEF Innocenti Research Centre (2012) warns, relative poverty is not a good metric for comparison across countries except for those wealthier nations where falling below 50% of the median income does risk social exclusion (a concept we define later in this chapter).

Poverty as lack of capabilities

> The capability approach . . . builds a bridge between absolute and relative concepts of poverty. It is absolute in identifying the capabilities or functioning that people should experience, but relative in the income or resources that may be required.

Reproduced from Labonté, R. et al., Indicators of Social Exclusion and Inclusion: A Critical and Comparative Analysis of the Literature, E/Exchange Working Paper Series, PHIRN, University of Ottawa, Canada © 2012, with permission from the author.

While relative poverty presents a more nuanced understanding of 'being poor' than does absolute poverty, it still relies upon indicators of income. Amartya Sen (1985), in his pioneering capability approach to poverty, focused attention on the infrastructural enabling conditions ('capabilities') that allow people to attain desirable states ('functioning'), without which a minimally dignified human existence is not possible. This has brought in different kinds of indicators that are much more transparent and direct reflections of people's actually achieved levels of well-being and ability 'to accomplish what [they] value' (Alkire 2002, p. 6, cited in Nunes 2008). Income is simply a means to a valued and socially purposeful end. Sen

considered indicators such as life expectancy, literacy, and infant mortality to be important proxies for capabilities (at least at a population level) and more useful than income alone to identify poor from non-poor groups or countries. He proposed that indicators of these other characteristics should be aggregated into a more complex poverty measure (Nunes 2008). This approach became the basis of the Human Development Index (HDI), first released in 1990 and issued annually by the United Nations Development Programme (UNDP), and which combines data on health, education, and living standards (this last dimension using the income indicator of log gross domestic product (GDP)/capita) (UNDP 2011). The capability approach from which the HDI arose has since been considerably elaborated (Ranis et al. 2007), including the UNDP's creation of a multidimensional poverty index (MPI) in which additional weighted measures have been added to its HDI (Box 2.3.1).

The key contribution the capability approach makes to public health is that it de-couples meaningful social participation (the concern of relative poverty) and, in broader conceptual terms, the notion of 'development' itself, from a purely or primarily economic growth/income growth model. It identifies a range of goods and services for which social (state) provision is important due to their cost or to market failures in ensuring equitable access. The capability approach arose, in part, to challenge the dominance in public policy of the GDP measure, which critics (Daly and Cobb 1990; Fioramonti 2017) argued was a deeply flawed indicator of how well countries were doing in providing for the general health or welfare of their citizens.

Box 2.3.1 Multidimensional poverty index

1. Education (each indicator is weighted equally at 1/6):
    - Years of schooling: no household member has completed 5 years of schooling.
    - School attendance: no school attendance in years 1–8.
2. Health (each indicator is weighted equally at 1/6):
    - Child mortality: if any child has died in the family.
    - Nutrition: if any adult or child for whom there is nutritional information is malnourished.
3. Standard of living (each indicator is weighted equally at 1/18):
    - Electricity: the household has no electricity.
    - Drinking water: the household lacks access to clean drinking water within a 30 minute walk from home.
    - Sanitation: the household has no adequate sanitation or only a shared toilet.
    - Flooring: the household has a dirt, sand, or dung floor.
    - Cooking fuel: the household cooks with wood, charcoal, or dung.
    - Assets: the household does not own more than one of: radio, TV, telephone, bike, motorbike, or refrigerator, and does not own a car or tractor.

While Sen (1999) argued effectively for the obligations on states to provide a minimum basket of resources allowing people to develop their capabilities (hence their choice of ‘functionings’, including choices concerning their health), his collaborator in developing this theory, Martha Nussbaum, attempted to identify the contents of that basket:

Life: being able to live to the end of a human life of normal length; not dying prematurely, or before one's life is so reduced as to be not worth living.
Bodily health: being able to have good health, including reproductive health, to be adequately nourished; to have adequate shelter.
Bodily integrity: being able to move freely from place to place; being able to be secure against assault, including sexual assault, having opportunities for sexual satisfaction and for choice in matters of reproduction.
Senses, imagination, and thought: being able to use the senses, to imagine, think, and reason—and to do these things in a way informed and cultivated by an adequate education, including but not limited to literacy and basic mathematical and scientific training. Being able to use one's mind in ways protected by guarantees of freedom of expression with respect to both political and artistic speech. Being able to search for ultimate meaning of life in one's own way.
Emotion: being able to have attachments to things and people outside ourselves.
Practical reason: being able to form a conception of the good and to engage in critical reflection about planning one's life; Nussbaum recognizes that this entails protection for the liberty of conscience and religious observance.
Affiliation: being able to live with and towards others; to engage in various forms of social interaction; having the social bases of self-respect and non-humiliation; being able to be treated as a dignified being including protection against discrimination on the basis of race, sex, sexual orientation, religion, caste, ethnicity, or national origin.
Other species: being able to live with concern for and in relationship to the world of nature.
Play: being able to laugh, or play, to enjoy recreational activities.
Control over one's environment both politically and materially, including having the right to political participation and having property rights on an equal basis with others, having the right to seek employment on an equal basis with others (Nussbaum 2000, pp. 77–80).

Defining poverty as capability-failure, especially given the long list of positively stated attributes of 'flourishing' that Nussbaum provides, nonetheless risks taking policy attention away from income poverty. In commodified, wage-based market systems, income (and its quantity) represents both choice (capabilities) and power (Lister 2004). Money may not be everything, but adequate income (however adequacy is determined)

remains basic to any understanding of poverty. We note that in some low-income countries market systems are less entrenched and access to the capabilities through subsistence farming and strong cohesive communities remain important protections against absolute poverty.

Poverty as deprivation

> Deprivation . . . exists when people lack or are denied resources to participate in social and economic activities in the society in which they live.
>
> Reproduced from Labonté, R. et al., *Indicators of Social Exclusion and Inclusion: A Critical and Comparative Analysis of the Literature*, E/Exchange Working Paper Series, PHIRN, University of Ottawa, Canada © 2012, with permission from the author.

Deprivation entered the poverty literature in the late 1960s (Yitzhaki 1979). Like poverty, deprivation has both absolute and relative conceptualizations. As an absolute condition, deprivation is an undesired state that arises when people are unable to access necessary goods and services due to a lack of resources (Hallerod 1996); much depends here on where one draws a line under 'necessary' which immediately takes us into the terrain of relative deprivation. As a relative condition, deprivation exists when people lack or are denied resources to participate in social and economic activities in the society in which they live (Bailey et al. 2004). One example is the UNICEF Innocenti Research Centre's measure of 'child deprivation' based upon the percentage of children aged 1–16 lacking two or more items from a list of 14 considered essential to acceptable child functioning in economically advanced countries (Fig. 2.3.4) (UNICEF Innocenti Research Centre 2012). Like relative poverty, the emphasis of relative deprivation is on social participation. The notion of being 'denied' resources for such participation is captured evocatively in deprivation as an 'enforced lack of socially perceived essentials' (Saunders et al. 2008, p. 175). Deprivation, like multidimensional poverty, can be multiple, when people lack access to sufficient levels of several attributes important to social participation, such as income, housing, healthcare, and education. Moreover, deprivation is an enforced state; that is, its origins can be traced directly to certain political, economic, or policy choices made by governments and which are entrenched in economic systems such as capitalism or, in more contemporary parlance, neoliberal globalization.

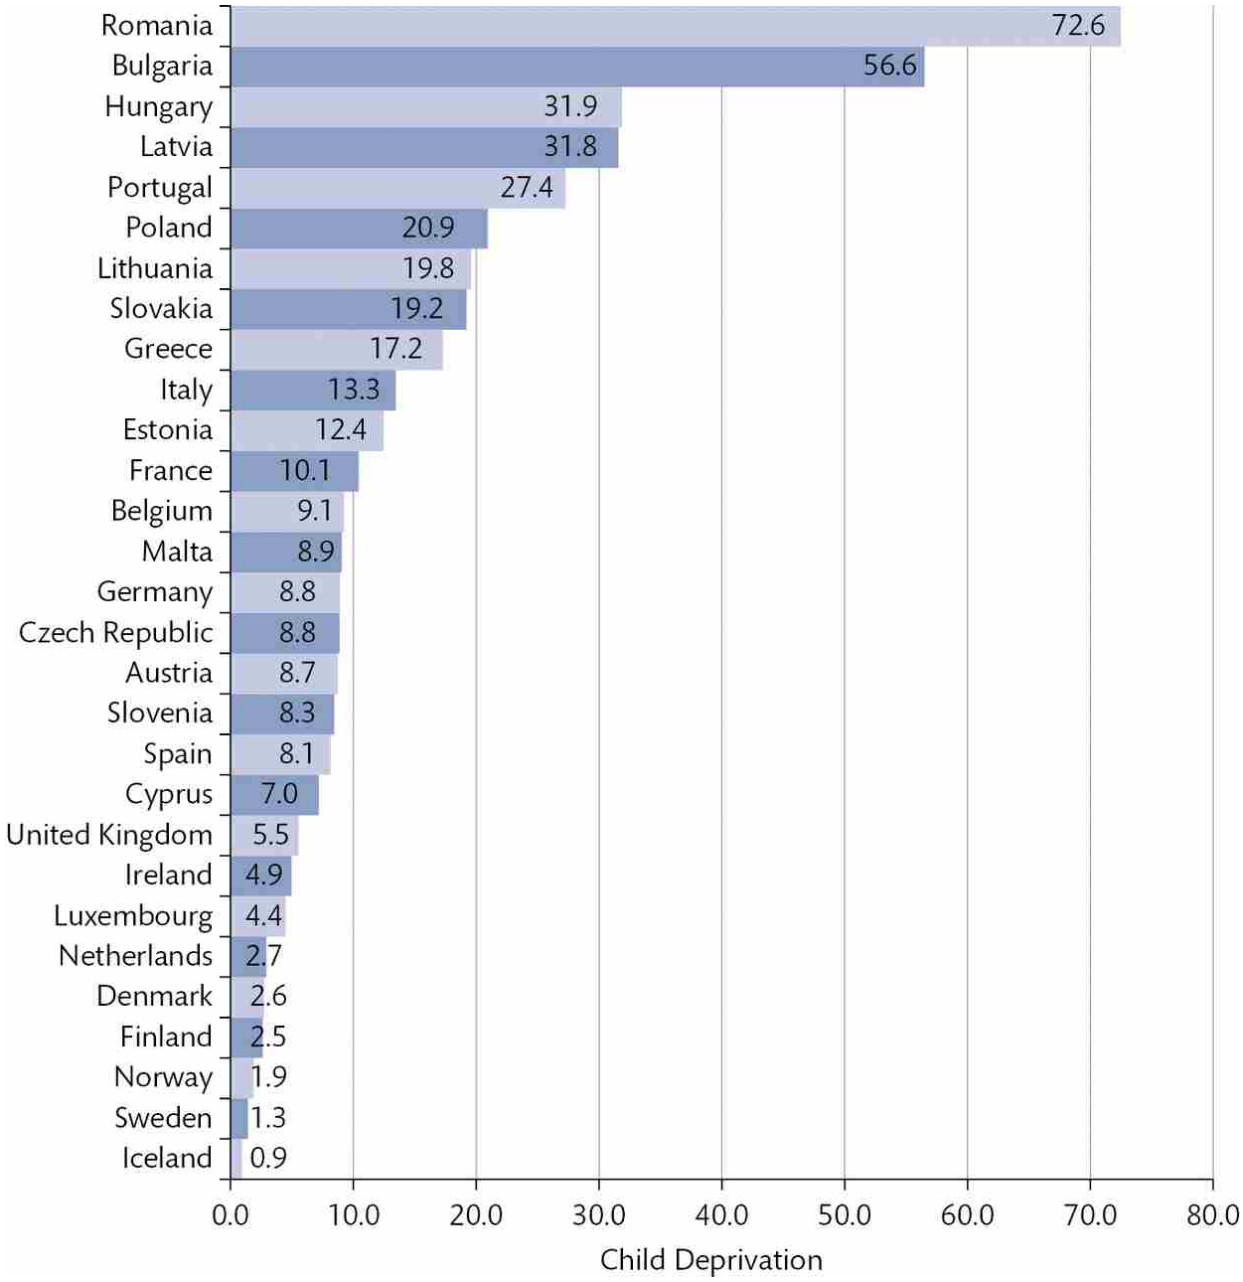

Fig. 2.3.4 Child deprivation in selected countries. Data for 2009.

While deprivation first emerged from the poverty literature, there are important conceptual differences between the two terms. A person may be poor in terms of income but not deprived in terms of, for example, housing,

healthcare, education, or transportation, to the extent these are publicly subsidized or provided. Conversely, a person could experience deprivation in multiple dimensions while not being income poor, such as experiencing discrimination by virtue of one's gender, ethnicity, or sexual orientation (Saunders et al. 2008). This intersectionality of social identity and health risk has become increasingly invoked as a way of incorporating a broader understanding of poverty and inequality, by exploring 'simultaneous intersections between aspects of social difference and identity (e.g. as related to meanings of race/ethnicity, indigeneity, gender, class, sexuality, geography, age, disability/ability, migration status, religion) and forms of systemic oppression (e.g. racism, classism, sexism, ableism, homophobia)' (Springer et al. 2012, p. 1661). It shifts an understanding of poverty well away from matters of simple material goods and physical functioning, which some critics argue deflects attention away from the financial needs of the many who live in absolute or relative poverty (Nolan and Whelan 1996), to a much broader concern with multiple forms of what has been termed social exclusion.

Poverty as social exclusion

> Poverty and social exclusion refer to when people are prevented from participating fully in economic, social and civil life and/or when their access to income and other resources (personal, family, social and cultural) is so inadequate as to exclude them from enjoying a standard of living and quality of life that is regarded as acceptable by the society in which they live. In such situations people often are unable to fully access their fundamental rights. (p. 11)

Reproduced from European Commission, *Draft Joint Report on Social Exclusion*, European Commission, Brussels, Copyright © 2001.

Social exclusion extends beyond poverty and deprivation concepts by incorporating a broader understanding of social processes and their consequences (Bailey et al. 2004). Both poverty and deprivation are components of social exclusion but, as Berger-Schmitt and Noll (2000) point out, income poverty can be both a cause and a consequence of social exclusion. But income poverty is only one possible cause or consequence. As with deprivation, one can be wealthy (not poor) and still experience social exclusion, as has been the case with LGBTQ+ (lesbian, gay, bisexual, transgender, queer/questioning) people in many of the world's countries (Estivill 2003). Social exclusion, although sharing much in common with Townsend's concept of relative deprivation, differs in the emphasis it places

on non-material aspects, from ‘prospects and networks’ (which work to reduce exclusion) to prejudice and discrimination (which work to increase it) (Saunders and Wong 2009).

Social exclusion first arose in research and policy discourse in France in the early 1970s, and was used both to explain the effects of extreme economic restructuring on social solidarity beyond what poverty and deprivation alone could describe, and to assist in developing policies to promote social cohesion within the European Union (Gore and Figueiredo 1997; Aasland and Flotten 2001; Rawal 2008). Rene Lenoir in 1974 was the first to coin the term as a way to define the condition of a large portion of the population that included the poor, handicapped, vulnerable, aged, abused children, substance abusers, and other marginalized groups or ‘social misfits’ (de Haan 1999; Sen 2000). A broader conceptualization was later proposed to incorporate the ‘social, economic, political and cultural systems which determine the integration of a person in society’ (Walker 1997, cited in Lessof and Jowell 2000, p. 5)—that is, the social processes of exclusion.

Economic exclusion is a term frequently used synonymously with social exclusion. Dertwinkel (2008, p. 4) argues that the ‘meaning of social exclusion has always been an economic and less a political or cultural one’ and defines economic exclusion as a state of ‘non-participation in or blocked access to the labour market, public services, finance, housing, educational and health sector, among other possibilities’ (Labonté et al. 2012, pp. 19–20). This emphasis on labour market attachment is most often encountered in European writing on social exclusion, even when other dimensions of exclusion are considered. Part of the reasoning behind this emphasis is that it creates greater social cohesion and reduces social conflict, given evidence that high levels of youth unemployment and poverty are associated in many countries with gang participation or rebel group involvement, motivated primarily by a desire to earn income (World Bank 2011). Other theorists, however, give greater attention to the relational aspects of social exclusion, linking exclusion to inadequate social participation, lack of social integration, and lack of power (Room 1995, p. 5). As Sen (2000, p. 6) puts it, social exclusion (unlike poverty or deprivation) gives ‘a central role to relational connections’. Work, like the income it generates, is simply one of the means of making such connections. This emphasis was echoed in the final report of the Social Exclusion Knowledge Network of the WHO Commission on Social Determinants of Health which distinguished between

‘social exclusion as a state experienced by particular groups (common in policy discourse) as opposed to the relational approach . . . [in which] exclusion is viewed as a dynamic, multidimensional process driven by unequal power relations’ (Popay et al. 2008, p. 7). This process results in unequal resources, reduced capabilities, and fewer claims on human rights leading to inequalities in access to entitled services. This perspective on social exclusion also points the policy spotlight at unfair economic and social structures rather than on deficiencies of individuals.

Gough et al. (2006) discuss social exclusion in terms of the ways in which it is an inevitability of neoliberal capitalism. They acknowledge that it is a highly ambiguous concept (Gough et al. 2006, p. 49), and one that can be used to support a neoliberal status quo by regarding as unproblematic the ‘inclusion’ of elite and wealthy groups whose privileges and practices contribute to the exclusion of others. They maintain that a broad notion of social exclusion should be centrally concerned with social oppression particularly those of ‘race’, gender, sexuality, disability, and age. Crucially for the discussion in this chapter they note that the discourse of inclusion avoids confronting the question of justice and that ‘one can be included in any social arrangement in an unjust fashion’ (Gough et al. 2006, p. 4). As Levitas noted:

> The term social exclusion is intrinsically problematic. It represents the primary division in society as one between an included majority and an excluded minorityThe solution is a transition across the boundary to become an insider rather than an outsider in a society whose structural inequalities remain largely uninterrogated. (Levitas 2005, p. 7)

Poverty summarized

Taking account of these various attempts to define and understand poverty, the concept might usefully be summarized as an absolute and comparative lack of resources and capabilities, comprised principally of the following:

Adequate material resources (food, shelter, clothing, and other normatively defined social necessities).
Income to acquire such necessities (generated through employment or government subsidies and transfers).
Access to formal labour markets or post-retirement or child-rearing income support (to provide adequacy and security of income, as well as access to social relations).
Access to adequate and affordable housing (extending beyond basic shelter to incorporate aspects of overcrowding, disrepair, insecure tenancy), and to services basic to health (e.g. sanitation, water).
Access to adequate and affordable educational and healthcare opportunities (to improve access to formal labour markets and reduce barriers to broader forms of social participation).
Socially conditioned and structured forms of discrimination (which reduce access to formal labour markets, educational and healthcare opportunities, and broader forms of social participation).
Power or voice to influence the policy choices of governments affecting all of the aforementioned conditions (which extends to lack of political freedoms or human rights) (Labonté et al. 2012, p. 15).

There are three cautions about poverty that need issuing. The first is that poverty mobility can be dynamic, with people moving in and out of income- or consumption-based poverty (whether absolute or relative) even within short time periods. The chronic poor are those who ‘remain trapped in situations and relationships which produce deprivation and capability losses over long periods’ (Policy Analysis Discussion Group 2012, p. 6). The second is that people living in poverty, however conceptualized or measured, may not view themselves as poor, deprived, or without capabilities. ‘Subjective’ poverty differs from its objective measure, and may reflect people’s perception of their agency, their rejection of the stigmatizing label of being one of ‘the poor’, or an internalized resignation to the inevitability of their circumstances. The third is that, just as poverty is now regarded as multidimensional, people’s identities and capabilities are multiple. A focus only on people’s relative deprivation without appreciating their relative capabilities risks creating or reinforcing resignation to their circumstances, rather than mobilization to change them.

Finally, persistently high rates of poverty (at the not-so-extreme level) need to be seen within a context of rising income and wealth inequalities.

Since the 1980s the income share of the top 10% has risen sharply in North America, China, India, and Russia; remained flat (but at excessively high existing levels) in sub-Saharan Africa, Brazil, and the Middle East; and increased slowly in Europe (UNCTAD 2018). When global inequality is mapped, it becomes an 'elephant curve', with the top 1% accumulating most of the income gains (Fig. 2.3.5). Given the environmental impossibility of eliminating poverty at any level through conventional 'trickle-down' economics, it is reassuring that one of the SDGs (SDG 10) specifically commits the world's governments 'to reduce inequality between and within countries' (Sustainable Development Knowledge Platform 2017). One of the goal's targets calls for sustained income growth for the bottom 40% (within countries and globally) at a rate greater than the average. Without addressing the capture of global income by an elite transnational capitalist class (the 1%, but more accurately the 0.01%), however, the bottom 40% might experience a relatively higher-income growth *rate* than the average, but in absolute dollar terms the gap between richest and the rest could continue to worsen. The imperative for national and global systems redistribution of income assumes paramount importance.

How does poverty affect health and ill health affect poverty?

> Whatever is going round, people in lower social positions tend to get more of it, and to die earlier even after adjustment for the effects of specific individual or environmental hazards. (p. 1355)

Reproduced with permission from *Social Science & Medicine*, Volume 31, Issue 12, Evans R. and Stoddart G., Producing Health, Consuming Health Care, pp. 1347–63, Copyright © 1990.

On average, the lower the socioeconomic position, the lower one's health status. Socioeconomic status (SES) is usually measured by income, occupation, or education, but also includes stratification by social class, gender, and race/ethnicity—examples of the intersectionality of different deprivations discussed earlier. One of the key findings in recent years has been that differences between social position and health status follow a gradient, a step-wise pattern between where one sits in a SES hierarchy and most health outcomes. Although not all health conditions follow a socioeconomic gradient (a few diseases are more common in higher than in

lower SES groups) the pattern is robust, observed in many countries, persists over time, and is evident for all age groups and for both men and women. Research has also shown that health inequities accumulate over a lifetime and that disadvantage at each stage of the life course affects health (Lynch et al. 1997; Smith et al. 1997, 1998). Adverse social and economic conditions in the early years of life are increasingly being shown to have a lifelong impact on health (Lynch and Smith 2005; Hertzman and Boyce 2010; Power et al. 2012). Much of this textbook is concerned with the determinants of the gradient in health; here, we recount briefly the three major explanatory models for this gradient: natural or social selection, cultural/behavioural, and materialist or structural (Baum 2008).

Natural or social selection

The social selection argument suggests that healthier people become wealthier people, enjoying greater social mobility than their poorer fellows. There is some evidence that better health is associated with social mobility, especially at younger ages; but this accounts for only a small portion of health differences between social groups (Whitehead 1992; Power et al. 1996). The social selection and mobility argument comes with its inverse: people are poor because they are unhealthy. Again, there is some evidence for this, particularly in low-income countries. We have already noted the problem of medical poverty, where the absence of affordable healthcare pushes sick people into poverty. There is also evidence that people living in countries with high burdens of particular diseases (such as HIV/AIDS, tuberculosis, or malaria) and with poor social protection safety nets (such as income transfers or sickness and unemployment benefits) can suffer greater poverty due to their illness reducing their ability to earn income. Poor health also contributes to poverty through its debilitating effects of inadequate nutrition on individual development and later economic productivity (Horton and Ross 2003; Sanders and Chopra 2007; Baum 2008). Early insults to the growth and brain development of children, even with intensive interventions later in life, are partially irreversible. In many cases, the damage is done even before the child is born. Undernutrition among mothers is a major reason why babies are born with a low birth weight, a result of small maternal size at conception and low pregnancy weight gain or inadequate food and energy intake during pregnancy (Kramer 1987). Malnutrition

among infant girls is therefore one of the main routes for the intergenerational transmission of poverty (Horton and Ross 2003).

That sick people become poor, in other words, reflects the same dynamics of social stratification and material circumstances that explain why poor people are more likely to become ill in the first place. This accounts for why some wealthy but highly unequal countries with limited social protection can have poorer population health outcomes than poorer but more equal countries with high levels of social programme spending (notably for primary healthcare, education, women's literacy, land reforms, and physical infrastructure) (Balabanova et al. 2011). Sen (1999, pp. 335–6) showed this very clearly when he compared the life expectancies in the early 1990s of US whites with US African Americans, and with Indians in Kerala and the Chinese. While African Americans are very many times richer in income terms than the people in China and Kerala (even after correcting for cost of living differences) they are less likely to live as long. Sen explains this by reference to 'the social arrangements and community relations such as medical coverage, public healthcare, elementary education, law and order, and prevalence of violence'. In other words: there is nothing 'natural' about 'social selection'; such selection arises as an effect of how the political and economic systems of countries are structured.

Cultural/behavioural explanations

A more commonly encountered reason for the SES gradient in health is that poorer people make unhealthier lifestyle choices. This is not a new argument. During the early decades of the nineteenth-century Industrial Revolution in Europe, with its dislocating impacts on rural agricultural livelihoods and explosion of ghettoes in rapidly expanding cities (a phenomenon now characteristic of many developing countries in late twentieth- and early twenty-first-century globalization) the poor were seen as a palpable disease threat to the rich. Their poverty, in turn, was not regarded as an effect of their economic dislocations, but as 'the interaction of the twin problems of indolence and vice' (Alcock 1993, p. 12). The British 'father' of public health, Sir Edwin Chadwick, in his reforms of the poor laws requiring urban paupers to earn their minimal allowance in workhouses, and so to become 'deserving poor', argued that:

> The population so exposed is less susceptible to moral influences, and the effects of education are more transient than with a healthy population; these adverse circumstances tend to produce an adult population short-lived, improvident, reckless and intemperate, and with habitual avidity for sensual gratifications. (Chadwick 1930)

Even while acknowledging the 'adverse circumstances' of the poor, Chadwick posits that the poor health of the poor results primarily from their lack of the proper behaviours and morality of the healthier and wealthier. A more socially critical observer of the same era, Friedrich Engels, agreed with Chadwick that alcohol was fairly prevalent among the poor labouring classes, but that 'it was almost their only source of pleasure':

> The working man comes home from his work tired, exhausted, finds his home comfortless, damp, dirty, repulsive; he has urgent need of recreation, he must have something to make … the prospect of the next day endurable. (Engels 1845/1999, p. 113)

The same dichotomy between a behavioural and a socially critical account of the poverty/health relationship persists today. Many (although not all) unhealthy behaviours do tend to be more prevalent as one moves down the social gradient. Even in developing countries undergoing nutritional transitions (where traditional diets are being replaced by increased consumption of high-sugar/refined carbohydrate, energy-dense, low-nutrient food commodities), what might begin as a status choice among a rising middle class quickly becomes a necessity choice (due to availability and cost) for poorer social classes (Drieskens et al. 2009; Monteiro et al. 2010; Stuckler and Nestle 2012). The same is true for smoking, originally more common among elite social classes, and, to lesser degrees, alcohol and other drug use (Drieskens et al. 2009). But explaining these behaviours as 'cultural' effects of poorer groups (their improvident or reckless 'lifestyle'), or as their lack of knowledge or motivation to adopt healthier patterns, ignores the social contexts that condition and constrain individual choice (Layte and Whelan 2009). It also fails to account for the excess disease burden faced by many poorer groups, even after accounting for all of the individual/behavioural risk factors (Lynch and Smith 2005).

Materialist or structural explanations

The limitation of a narrowly behavioural understanding of the poverty/health relationship draws attention to how the material conditions of poverty affect health. Here the enumeration of, and evidence for, the health determining

effects of these conditions is plentiful, reflecting many of the material circumstances identified in this chapter's discussion of poverty and deprivation: access to income, housing, employment, nutritious food, safe water and sanitation, unemployment protection, health services, education services, and other socially provided resources that allow for the development of capabilities. These structural factors (so named because they reflect embedded economic and power relations within societies) are also related to what have been called psychosocial risk factors: the isolation, low social support, poor social networks, high self-blame, and low perceived power that are more frequent among poorer and less educated groups (Najman 1994; Lynch and Smith 2005; Kawachi et al. 2008). Racism has also been shown to have a powerful effect on health status (Krieger 2000; Paradies 2006; Ziersch et al. 2011), psychosocial and material risks cluster together, and poorer groups (those lower along the SES gradient) are more likely to experience all three. In countries where material inequalities have been significantly reduced through welfare measures, for example, health inequalities experienced by poorer groups are more likely to be a result of greater behavioural and psychosocial risks; although, as Johan Mackenbach suggests, 'the persistence of health inequalities in modern European welfare states can partly be seen as a failure of these states to implement more radical redistribution measures' (Mackenbach 2012, p. 761; see also Chapter 2.4). Behavioural, psychosocial, and material risks matter and interact with each other (Krieger 2000; Paradies 2006; Ziersch et al. 2011).

What theories of justice should guide our interventions?

The public health concern with justice, poverty, and health enjoys a rich history. Over 150 years ago the young Prussian physician, Rudolf Virchow, hired by the government to recommend how to control a typhoid epidemic among poor coal miners, famously called for massive social reforms that ranged from progressive taxation and organized food cooperatives, to improved wages and working conditions, strong local government, improved education, and an end to church interference urging the poor to suffer now and to reap their rewards in heaven. Friedrich Engels, writing around the same time as Virchow, published his lengthy analysis of The Condition of the Working Class in England, leading to his co-authorship with Karl Marx of the influential Communist Manifesto with its call for a revolutionary

social justice. Some of this early concern with poverty and its social and physical ills continued into the late nineteenth and into the twentieth century, although it became muted by the rise of 'scientific medicine' and its promise of a cure for most diseases. Supported by industrialist philanthropies (notably in the Americas, by The Rockefeller Foundation), scientific medicine's emphasis on cure rather than prevention deflected much public health attention away from the social roots of disease (Brown 1979; Tesh 1988). Poverty as a public health issue occasionally surfaced, especially during times of economic recession or depression when high poverty rates were associated with the spread of diseases such as tuberculosis and cholera. But it was in Latin America that the radicalism of nineteenth-century public health activism became institutionalized in the practice of what has been called 'social medicine' (Waitzkin 2005). One of its major proponents was the Chilean physician (and later socialist President) Salvador Allende who, as health minister in the late 1930s and 1940s, approached health inequities in Chile as a direct result of historic underdevelopment, international economic dependency, and foreign debt. He argued that the 'medico-social problems of the country … require precisely the solution of the economic problems' (Waitzkin 2005, p. 740). Allende's reforms, echoing those of Virchow, included wage improvements, wealth redistribution, land reforms, improved food security measures, and publicly supported housing development.

More recently, the WHO Commission on Social Determinants of Health (2008) took a clear stand that inequities in health (avoidable inequalities) were unacceptable and the goal of policy should be to eliminate these and so argued for closing the life expectancy gap in a generation.

These are bold public health proposals, generally framed in broadly stated concerns with justice (fairness). But how should we determine when poverty's health risks become unacceptable? What theories of social justice might guide our public health interventions or advocacy?

Equality of opportunity or equality of outcome?

Social justice theory is generally associated with European societies and particularly with struggles during the industrial revolution and the emergence of socialist, social democratic, or other models of redistributive welfare states: 'Social justice is not possible without strong and coherent

redistributive policies conceived and implemented by public agencies' (United Nations Division for Social Policy 2006, p. 6). Social justice theory is essentially concerned with equity, or fairness. On this basis, it is argued that social justice (equity) is a universal concern, since all social arrangements, to be legitimate and to function at all, must attend to issues of equality (Sen 1992). But there are subtleties to how equity is conceived with two main dimensions: equality of opportunity, achieved through procedural justice or 'horizontal equity' in which equals are treated the same; and equality of outcome, achieved through substantive justice or 'vertical equity' in which people are treated differently according to their initial endowments, resources, privileges, or rights. Both equalities (opportunity, outcome) are ideal types; neither exists in 'true' form. They represent aspirational ideals of what societies strive to create for their members (fairness in outcomes) and how they believe this should be accomplished (fairness in opportunity) (Labonté 2010, p. 84).

There is a political, as well as philosophical, difference in these two broad social justice streams (Labonté 2010, p. 84). Recent decades of global market integration and the collapse of Soviet-style 'socialism' have been accompanied by the increasing dominance of neoliberal ideology which has supplanted concerns with social justice by an exclusive focus on economic growth which, it is suggested, will eventually result in greater and better-distributed wealth—the trickle-down theory.

In turn, proponents of more open markets and conventional approaches to growth and development emphasize equality of opportunity, with only residual attention to equality of outcome. This was the position taken by the World Bank's 2006 World Development Report on the theme of equity and development, which was less supportive of post-market income redistribution to achieve greater equality, instead favouring greater individual equality of opportunity through inter alia 'equality before the law, equal enforcement of personal and property rights, non-discriminatory institutions, and equal access to public services and infrastructure' (World Bank 2006, pp. 18–19). The slight nod to a concern with outcomes was reference to avoidance of absolute deprivation (Labonté 2010, p. 84).

Theories of justice

Moral defence for some mitigation of health and social inequalities arising from poverty is a recurrent theme in much contemporary Western philosophy. Peter Singer (1972) posits 'a Greater Moral Evil Principle', that it is both just and of collective benefit to act to relieve poverty and deprivation if, in doing so, we do not sacrifice something of comparable moral significance. Around the same time John Rawls published his highly influential Theory of Justice. Standing behind a 'veil of ignorance' as to their social standing at birth, Rawls argues that people would choose a justice that guaranteed a minimum of primary goods that any rational person would choose as basic to their needs. This justice theory builds upon two principles. The first principle is the 'priority of the equal' (basic liberties), which roughly equates with individuals having civil and political rights that protect them against excess authoritarian rule by the state. The second principle is based on legal equality of opportunity, which roughly equates with individuals having economic, cultural, and social rights that obligate states to provide certain goods or services (the minimum resources or capabilities required to exercise one's functioning). His second principle also invokes the 'difference principle': that inequality in the distribution of social and economic goods ('primary goods') are allowable only to the extent that they also improve the lot of the least advantaged. The difference principle obliges a degree of state interventions of redistribution and regulation, although Rawls did not believe that the extreme differences in wealth and power that markets create was of moral concern provided the conditions of the least advantaged improved. He also emphasized the centrality of better procedural justice (Schaefer 2007; Labonté 2010, p. 85).

Rawls' justice theory is located within the social contract school, which views nation states as the primary actors in international relations. He held that poverty in low-income countries was primarily an effect of domestic policies and practices with little international or global causality. Pogge (2002), drawing on cosmopolitan arguments, challenges Rawls on this conclusion, as well as on evidence that poverty cannot be de-linked from global economic institutions and actors. In doing so, he extends Rawls' basic justice theory to a global level, contending that there are not simply 'positive duties' to assist those in need, but moral obligations (negative duties) to prevent harm (Pogge 2004). Pogge's theory of relational justice (Pogge 2002) is based on three lines of argument:

The radical inequalities observed between peoples and nations today are partly an effect of a violent history in which some gained at the expense of others. While we individually cannot be held responsible for the actions of our forebears in this 'conquest', as moral persons we can be held accountable for rectifying the vast disparities in initial conditions that this history has created.

Not only does procedural justice by itself fail to account for these vast disparities in initial conditions; it is impossible to conceive of these disparities existing on the scale that they do without 'an organized state of civilization' (Pogge 2005) to uphold them. Both procedural and substantive injustices thus endure.

There is evidence that economic institutions operating on an international scale (the 'organized state of civilization') have been complicit in upholding these injustices. There are also feasible alternatives to these economic institutions that would reduce the 'radical inequality' of persisting poverty. Persons involved in upholding these institutions are thus implicated in creating subsequent ill health, even though they may be half-way around the world (Pogge 2004).

Pogge concludes that: 'we are *harming* the global poor if and insofar as we collaborate in imposing an *unjust* global institutional order on them'; and proceeds to offer an evidence-informed argument to establish that present global institutional rules and procedures are unjust (Pogge 2005, emphasis in original). The justice implication is one of immediately engaging in 'rectification' through strengthened human rights and more progressive systems of global resource redistribution; but also an obligation to change the very rules of economic governance in order to overcome the historic and radical inequalities in initial conditions (Labonté 2010, pp. 85–6).

A similar theory of social justice has been argued by Iris Marion Young. Accepting that there are demonstrable 'structural injustices' that 'put large categories of persons under a systematic threat of domination or deprivation of the means to develop and exercise their capacities, at the same time as these social processes enable others to dominate' (Young 2006, p. 114), Young argues that 'all agents who contribute by their actions to the structural processes that produce injustice have responsibilities to work to remedy these injustices' (Young 2006, pp. 102–3). Her 'social connection model' of responsibility extends these moral obligations beyond those more directly (causally) liable to a larger body of people who may be only indirectly

connected. An example she offers is responsibility for retaining developing country ‘sweatshops’, which includes those who shop at retailers sourcing their goods from such shops as well as the retailers and factory owners themselves. The limitation of Young’s argument is that its extensive diffusion of responsibility may limit the ability to enforce changes in practice.

The role of human rights

Several justice theories make reference to human rights. Not only do human rights conventions, ratified by most of the world’s states, represent a consensus on citizen rights and state obligations (Mack 2009), but there is widespread agreement that ‘poverty is the principal cause of human rights violations in the world’ (Office of the High Commissioner for Human Rights 1999, para. 9) and that ‘poverty constitutes a denial of human rights’ (Office of the High Commissioner for Human Rights 1999, para. 1). First established after the Second World War with the UN Declaration on Human Rights, several subsequent conventions have been agreed upon that detail specific citizen rights and state duties. These include the Covenant on Civil and Political Rights (intended to protect individuals against abuses of state authority) and the Covenant on Economic, Social and Cultural Rights (intended to guarantee individuals certain entitlements from the state); as well as specific treaties on the rights of children and women, racial minorities, indigenous peoples, and numerous other facets of social justice. Together these treaties comprise an ‘International Human Rights Framework’ which, although lacking enforcement measures, empowers different UN committees and ‘special rapporteurs’ to review countries’ compliance with their legally binding obligations. Central to concerns with the poverty/health relationship is Article 12 of Covenant on Economic, Social and Cultural Rights (technically known as the Right to the Highest Attainable Standard of Physical and Mental Health, see Chapter 3.3) and its General Comment 14, which identifies a broad range of actions required for the progressive realization of this right. Health is considered a basic right, since it is foundational to the enjoyment of most other human rights.

The right to health, when adopted in countries’ own constitutions or laws, however, can be and has been interpreted in legal decisions or national policy as an individual right only. Individual rights to treatment have been

used to force public payment of costly medicines with opportunity costs to other facets of public health access of greater importance to the poor (Hogerzeil et al. 2006; Gianella-Malcam et al. 2009; Yamin and Parra-Vera 2009). International legal scholars argue that human rights emphasis, instead, should be placed on populations who are poor and living in vulnerable circumstances. This requires greater attention to collective rights. Collective rights are implied in General Comment 14 on the right to health (Committee on Economic Social and Cultural Rights 2000), and are explicit in the Declaration on the Right to Development (Office of the High Commissioner for Human Rights 1986). Though the right to development is not a binding treaty, it is considered to have some standing in international human rights law (Aguirre 2008) and has strong normative support through UN agencies especially in the context of the Millennium Development Goals.

Some activist scholars and civil society organizations argue against the present international emphasis on human rights for its lack of class and political economy analysis. Others contend that human rights, with their individualistic and legalistic focus, 'are not sufficient to serve as ethical criteria in solving the fundamental problems of the absolute poor' partly because within these static statements, the 'poor are not invited . . . to articulate their moral needs and rights for themselves' (Mack 2009, p. 11). At the same time, human rights are considered the most globalized social justice statements of the post-Second World War era; and human rights treaties are being used to advance policies to improve health and to assist people living in poverty (Dasgupta 1995; Schrecker et al. 2010).

Inequalities in initial conditions

Confronting inequalities in initial conditions (the lives people are born into) is vital especially given the evidence cited earlier on the lifetime impact of adverse living circumstances in early life. A focus on initial conditions begins to blur the earlier distinctions between equality of opportunity (procedural justice) and equality of outcome (substantive justice). Equality of opportunity, to be just, requires vertical equity: a disproportionate provision of public goods and capability resources for those whom history's conquests, and today's political institutions, place in highly unequal initial conditions. Departing from the redistributive minimalism of the World

Bank's 2006 World Development Report, a later report of the Bank's Latin American Development Forum argues that:

> A better understanding of the importance of inequality of opportunity in the determination of inequality of outcomes may change attitudes towards redistribution. People dislike and consider unfair inequalities associated with differences in circumstances, which many argue should be compensated for by society. By highlighting that component of inequality attributable to circumstances, this type of analysis can help build a social and political consensus on … the best means for addressing inequality of opportunity. (p. 50)

What remains at issue is the extent of moral (or legal) obligation for amelioration of gross inequalities in initial conditions that create 'shortfall inequalities in central health capabilities' (Ruger 2008, p. 440). Is there an ethically defensible scale of rectification?

There is no answer to this question, apart from the imperative to seek one. In this quest, norms of procedural justice re-assume importance. Boggio (2009), in an argument for why international organizations and those within them have an ethical obligation to act to redress systematic health inequalities arising from poverty, addresses how such policy decisions can be made in a just manner. He identifies three basic principles for an 'ethically-informed deliberative process': publicity (transparency in process, a comprehensible rationale, and public argument and evidence); relevance (trust in actors/institutions by recipients, opportunity for wide participation, and interventions based on recipients' needs, values and aspirations); and revisability (policies and programmes can be challenged over time and improved, and individuals and institutions can be held accountable) (Boggio 2009). Several of these conditions are similar to principles of good governance widely held by governments and multilateral organizations (Governance Institute of Australia 2017; Lee et al. 2009); that is, they can be considered as having a broad normative base.

What public policies will reduce poverty?

> The last decade of research on the causes of chronic poverty has shown that a key factor in keeping certain categories or social groups in a state of chronic poverty (transmitted through the generations) is the operation of power relations which stigmatise the people involved, undermine

> their confidence, and systematically close off options for individual or collective advancement . . . A stronger focus on structural inequalities, on systematic obstacles to redistributive processes and on social groups and interactions between them is part of this. (p. 6, emphasis in original)

The first issue public health confronts in grappling with the poverty, health, and justice relationship is simply this: if it is possible to improve the health of those living in poverty without necessarily reducing income inequalities or relative poverty, is this sufficient? Some of the justice theories cited earlier might be content with saying yes to this, as their emphasis was more on absolute than on relative poverty. More recent poverty theories (capabilities, social exclusion/inclusion), however, give greater emphasis to the core value of ensuring human dignity or 'flourishing'. There is no justice if one simply survives; one must be able to live with purpose and meaning. Public health concern with poverty, then, extends beyond simply the specific disease risks poverty creates, to the existence of poverty itself—both absolute and relative.

The existence of poverty is inherently political, and there are different political theories for how poverty might be reduced. Alcock (1993) distils these to four dominant models: neoliberalism, conservatism, social democratic, and socialist, to which Gough et al. (2006) add a fifth: the associational.

The neoliberal model is associated with policy responses to the declining profit rates, economic recessions, and developing world debt problems that arose in the 1970s and 1980s. Promoted by conservative governments in the United Kingdom, United States, and Germany (in the 1970s, the major economic powers in the world), neoliberalism is based on a belief that free markets, sovereign individuals, free trade, strong property rights, and minimal government interference is the best means to enhance human well-being. Its policy platform rested on what became known in later years as the 'Washington Consensus': privatization, deregulation, tax reform (lower corporate and marginal rates), deficit reduction, and trade and financial liberalization. In general, the neoliberal view is that governments should avoid poverty reduction as a policy matter, and instead rely upon economic growth through stronger free markets and economic liberalization to 'trickle down' and lift the poor out of their condition. Extreme neo-liberals have argued that the state should not interfere at all with conditions of poverty

(Murray 1984), although this was rarely pursued as a policy option. Instead, neoliberal-dominated governments tend towards a 'welfare minimalism', with benefits or entitlements at a level that prevents the worst forms of deprivation, but that is rarely sufficient for 'flourishing' or 'health capabilities'. Increasingly punitive conditionalities are demand of people receiving welfare payments which increase the stigma and hardship of relying on the welfare system.

The conservative model overlaps with the neoliberal, although it holds to the importance of some state intervention to ameliorate the worst inequities arising from markets, and specifically market failures (Alcock 1993). Persisting chronic poverty is symptomatic of market failures, implying that free markets and economic growth are unable, by themselves, to create equal opportunities for all. Conservative policies are not aimed at preventing poverty, which would require strong regulation of markets, but with relieving the worst of its effects. The approach is selective (means-tested benefits), often punitive (distinguishing between the 'deserving' and the 'undeserving' poor, the latter being people who could work even if their employment kept them in relative poverty), and minimalist (offering supports well below the minimum wage that could be earned in work, thus creating an incentive to 'labour market attachment').

The social democratic model, historically associated most with northern European countries, but also found in other parts of the world, emphasizes universalism in its poverty reduction policies. Social democracies are often highly interventionist in markets to prevent poverty in the first instance, as well as using high taxation and social spending to reduce residual levels of poverty. As with the previous two models, there is still an emphasis on labour market participation and an expectation that those who can engage in work will do so. But there is also greater emphasis on extending positive incentives to people entering lower-waged positions to overcome what has been called the 'welfare wall', a term that describes the loss of non-income benefits when moving off social assistance to minimum waged positions. Although universalism in benefits and entitlements helps to build cross-class solidarity, the non-income benefits of social spending (e.g. in healthcare, education, transportation services, and the like) can be disproportionately 'captured' by wealthier social groups. This has led to calls for 'proportional universalism' in which policies are constructed such that those in greater need enjoy disproportionate levels of benefits (Marmot 2010); and for some

degree of targeting of benefits to maximize their poverty-reducing efficiencies (OECD 2008).

The associational model also reflects opposition to neoliberalism and is based on the need to involve people in economic models and reduce the extent to which they are alienated by them (Gough et al. 2006). Building strong social capital, voluntary organizations, and civil society are considered to be the key poverty-reducing components. Micro credit banks such as the Grameen Bank are an example in low-income countries where (mainly) women can obtain loans to set up their own business. A further example is the Indian Self-Employed Women's Association, which organizes millions of women to provide their own banks, workers' cooperatives, childcare, and health and unemployment insurance. In rich countries, examples would be locally based bartering systems, food, and worker cooperatives. These initiatives are based on self-help, are democratically run, have a local focus, and depend on forms of collectivity that can be plural, multiple, and diverse. Gough et al. (2006) indicate that the expectation is that states should be subordinate to these myriad local organizations and that political democracy should grow out of the practical economic and social democracy. They go on to note that associationalist projects are usually hemmed in by disciplinarian capital and the localist strategies leave the power structures that create poverty in the first place untouched.

The socialist model, though less prominent in recent decades since the collapse of the Eastern Bloc countries, holds that capitalist market systems inevitably create poverty and that the only enduring means to reduce poverty is to replace capitalism with a socialist system of governance. This implied a radical transformation of capitalist labour markets, which inevitably create unemployment and poverty, to socialist (collective) forms of production and ownership. In the absence of a political revolution, the entrenchment of neoliberal politics and ideology means that a process of transition to a socialist society needs to be envisaged. Moves towards greater egalitarianism include: protection of workers' conditions and rights; progressive taxation and tax enforcement measures for the wealthy and corporations; combating the multiple forms of discrimination in jobs, housing, and public services; withdrawal of public support for private education and health; public provision of good quality education and health services; provision of universal lifelong social security for all citizens; and maintaining public spaces for community use. Many of the critiques of

market economics made by socialism are finding more policy and media traction in the wake of the 2007 global financial and employment crises; accompanied by civil society calls for progressive taxation, stronger market regulations, and enforceable citizen rights to hold government to account (Labonté and Schrecker 2009). The election of Donald Trump as the US President in 2016 has also seen increased protest around the world against the extreme neoliberalism behind the policies his Presidency is implementing. There are also strong protests against the austerity agenda in European countries especially in Spain and Greece.

The role of policy initiatives and civil society mobilization for poverty reduction and fairer societies

Most countries have organized civil society groups, including labour organizations, campaigning for policy actions to reduce poverty. These groups generally blend the broad approaches of the social democratic and revolutionary socialist models. They often provide detailed policy analyses and briefs, and collaborate with some academic researchers to ensure the empirical and theoretical integrity of their work (Global Health Watch 4). Some groups focus on reducing poverty while others argue that poverty reduction will only result from a broader reform of the economic system and the inequities to which it gives rise. There are several examples in history of social and labour movement mobilization forcing changes in government and social policies, including those directly related to poverty reduction and health improvement (Szreter 2003). We offer two here, one a governmental example and the other capturing civil society activism.

Brazil's governmental reforms

Significant gains in poverty reduction, health system development, and health outcomes have been achieved in several countries through progressive social policies, resulting ultimately from political mobilization. Brazil's progress since the mid-1980s over the first 25 years of democratic government provides a contemporary example of progressive change within a market economy (see Chapter 2.5). Infant mortality, for example, fell from 114 per 1,000 live births in 1970 to just 19.3 per 1,000 live births in 2007,

while life expectancy at birth increased by almost 40%, reaching 72.8 years in 2008. It is not possible (or even likely) to attribute these impressive advances to health sector activities alone, since these activities were part of several large-scale social reforms initiated in the country. These reforms led to steep increases in school attendance and decreases in illiteracy rates, both of which are pathways to better health. As well, Brazil's GDP doubled between 1981 and 2008, potentially lifting more families out of income poverty; and its high levels of income inequality fell substantially as a result of such social policies as the Bolsa Família conditional cash transfer programme, which covers 10.5 million families, and increases in the legal minimum wage. Other social determinants of health were also improved substantially, including increases in provision to households of indoor water, sewage disposal, and electricity (Paim et al. 2011). Sustained and significant investment in the creation of a universal health system, the centrepiece of which is the Family Health Programme, is mostly directed at providing more accessible and equitable health services, particularly at the primary level, but also engages community health workers who identify in their localities social factors that negatively affect socioeconomic and health status and enrol other sectors in addressing them (Macinko et al. 2007; People's Health Movement et al. 2011).

The political context of Brazil's reforms dates back to the late 1980s when popular mobilization challenged a conservative government with strong pro-market policies. This mobilization against a military dictatorship brought together oppositional political parties (at the time, illegal), grassroots groups, progressive academics and researchers, and trade unions. This movement catalysed the institution of many progressive health policies. With the election of the Workers' Party in 1989, popular mobilization waned as progressive social policies were introduced, while 'social participation' in local government continues through such bodies as the National Health Council, which plays an ongoing role in democratizing policy development (Paim et al. 2011). In 2013, 'middle-class' protests began once again in Brazil, which some attribute to the country's targeting of many of its social reforms to the poorest sectors of the population. The challenge becomes how to universalize the benefits of these reforms, building the cross-class solidarity that remains important in sustaining support for redistributive social protection programmes (People's Health Movement et al. 2011).

Brazil entered an era of uncertain politics in 2017, following what some have described as a 'judicial coup' that removed the elected President and replaced her with a conservative politician and the subsequent imprisonment of the previous President Lula, in part following disenchantment by higher-income groups in the country with Brazil's policy directions, and widespread concerns over perceived government corruption (Saad-Filho 2016). The country's remarkable health system improvements, and the role of civil society activism in initiating and supporting these, still stands; as does the health and social justice activism of many civil society organizations within Brazil.

Civil society challenges to unhealthy globalization

Another important example of civil society activism that catalysed far-reaching policy change that indirectly impacts on health equity is the campaign against the Multilateral Agreement on Investment (MAI). The Association for the Taxation of Financial Transaction for the Aid of Citizens (ATTAC) was founded in France in 1998 to mobilize support for the Tobin tax on currency transactions as part of a broader movement against inequitable globalization arising from cross-border speculative finance. ATTAC, which has now established itself in many countries, played a leading role in France's decision to withdraw from OECD talks on the MAI, resulting in the failure of the talks (Waters 2004).

The People's Health Movement (PHM), another global civil society group, is a grassroots organization linking health activists around the world. It was formed following the First People's Health Assembly in 2000 and its political position is outlined in the People's Charter for Health (People's Health Movement 2009) and summarized in the Preamble as:

> Health is a social, economic and political issue and above all a fundamental human right. Inequality, poverty, exploitation, violence and injustice are at the root of ill-health and the deaths of poor and marginalized people. Health for all means that powerful interests have to be challenged, that globalisation has to be opposed, and that political and economic priorities have to be drastically changed.

The Charter goes on to call for much broader political, economic, and social participation from poor people. Since 2000 the PHM has grown to

encompass around 80 national circles of varying size and weight which are organized into regional networks. A Right to Health campaign, whose parameters have been defined at a global level but whose country-level activities vary according to context and conjuncture, has placed the responsibility for poverty reduction and the reduction of health inequities firmly on the shoulders of national states and international organizations. PHM has also collaborated with other organizations to produce five editions of the publication, 'Global Health Watch' (http://www.ghwatch.org), which present alternative and more progressive versions of the World Health Reports produced by the WHO. The GHWs provide a critical 'watch' on international organizations relevant to global health policy and governance including the World Bank, the WHO, and the Bill and Melinda Gates Foundation; offer evidence-informed critiques of neoliberal globalization; and argue strongly for its replacement by a more just and equitable system of global governance and economic system to achieve poverty eradication and health equity.

Conclusion

This chapter has analysed the various definitions of poverty and considered their philosophical and political implications. We have examined a variety of explanations for why poverty affects health adversely. On the basis of this examination we concluded that poverty reflects structural features of global and national economic and social systems and, in particular, that unequal societies give rise to greater poverty and suboptimal health outcomes. We examined the norms of justice that can guide policy interventions to reduce poverty and its causes. We argued that both equality of opportunity and outcome are essential considerations in public policy and that confronting inequalities in initial conditions is vital. Political responses to poverty reflect philosophical and ideological positions. Social democratic and socialist responses place emphasis on tackling the underlying structural causes of poverty and seek to provide non-stigmatizing supports to those living in poverty. Socialism also seeks to replace capitalist modes of production with those that socialize both production and profits and argues that a transition to such an economy would result in a significant reduction in poverty. Despite the efforts of many civil society groups around the world, poverty or near poverty, and its health consequences, although showing recent decline, are

still the reality for about half of the world's population. This fact, together with growing economic inequities, does suggest that a new world economic and social order is required to dramatically reduce or eliminate poverty and the adverse health outcomes to which it gives rise.

Socioeconomic inequalities in health in high-income countries

The facts and the options

Frank J. van Lenthe and Johan P. Mackenbach

Introduction to socioeconomic inequalities in health in high-income countries

In the first decades of the twenty-first century, socioeconomic inequalities in health still represent one of the greatest challenges for public health worldwide. This chapter aims to review the available evidence on the magnitude and explanation of these health inequalities (the 'facts'), and to present the available evidence on what can be done to reduce health inequalities (the 'options'). Socioeconomic inequalities in health will be defined as systematic differences in morbidity or mortality rates between people of higher and lower socioeconomic status, as indicated by, for example, level of education, occupational class, or income level.

This chapter only deals with the situation in high-income countries. Wherever possible, we will draw upon international overviews, such as comparative studies, in order to avoid biases related to the selective experiences of single countries. Most of the illustrations will be drawn upon the European experience, which has become very well documented in the past three decades.

An active interest in health inequalities in Europe can be linked to the publication of the Black Report in England in 1980 (Department of Health and Social Services 1980), which has been followed by an enormous rise of descriptive studies in many other countries, testifying to the existence of substantial inequalities in health in all countries with available data. Gradually the emphasis of academic research in this area has shifted from description to explanation, not only to satisfy scientific curiosities, but also to find entry-points for policies and interventions to reduce health inequalities. As a result, our understanding of the causes of socioeconomic inequalities in health has expanded tremendously, and has allowed interested policymakers to start searching for strategies to reduce these inequalities. The World Health Organization has actively promoted the issue of health inequalities by creating a Commission on Social Determinants of Health that has issued a major report urging policy action to 'close the gap in a generation' (Commission on Social Determinants of Health 2008). In some countries political windows of opportunity have arisen which have led to national programmes to tackle health inequalities. Evaluations of the most ambitious of these programmes (the 'English strategy') point to a need to double our efforts to find effective interventions and policies that can be implemented on a sufficiently large scale to achieve population-wide impacts (Mackenbach 2011).

The facts: description

Socioeconomic status (SES) should preferably be measured by individual-level indicators like education (e.g. highest completed level of education), occupation (e.g. occupational class), or income (e.g. household income adjusted for household size). Usually, all these indicators point in the same direction, with health being worse for those in lower socioeconomic groups, but there is often

substantial variation between indicators in the strength of the association, suggesting that the underlying etiological mechanisms are different as well. There is no ‘best single measure’.

The magnitude of socioeconomic inequalities in health can be measured in different ways, ranging from simple measures like rate ratios and rate differences (indicating relative and absolute differences in morbidity or mortality rates between two contrasting groups), to more complex measures like the relative index of inequality and the slope index of inequality (indicating relative and absolute differences in rates between those with the lowest and highest SES, taking all groups into account and calibrating the social position of each group to its relative size) (Mackenbach and Kunst 1997). Although the choice of measure will partly depend on technical considerations, each emphasizes different aspects of health inequalities, often at the expense of others, and it may therefore be important to combine different measures.

Socioeconomic inequalities in health usually present themselves as a gradient, in the sense that there is a stepwise increase of rates of morbidity and mortality with every step down the social ladder, implying that social inequality affects the health of nearly everybody, not only the worst-off.

Mortality

Total mortality

Evidence shows that mortality rates are higher among those in less advantaged socioeconomic groups. According to a cross-national comparative study, the relative index of inequality is greater than 2 for men in a number of European countries in the period around 2005–2009, indicating that mortality rates are twice as high for those in the lowest as compared to the highest educational groups (Table 2.4.1). For women, relative inequalities are reasonably similar or slightly lower (Mackenbach et al. 2016).

Table 2.4.1 Relative indices of inequality and slope indices of inequality of all-cause mortality by education, by country and sex, ca. 1990–4 and ca. 2005–9

Reprinted from Mackenbach J.P et al. (2016) 'Changes in mortality inequalities over two decades: register based study of European countries' *BMJ* 2016;353:i1732, with permission from the BMJ Publishing Group.

The magnitude of these inequalities varies substantially among European countries. For example, in the period around 2005–2009, the relative index of inequality for men is less than 2 in Scotland, whereas it is more than 3 for men in Lithuania. Education-related relative inequalities in mortality are smaller than the European average in all southern European populations and larger than average in most countries in the eastern and Baltic regions. Similar patterns are seen for occupation-related inequalities in mortality among middle-aged men (Mackenbach et al. 2008).

Within Europe, the international pattern observed for relative inequalities in mortality also applies to absolute inequalities in mortality, as indicated by the slope index of inequality. This is because countries with larger relative inequalities in mortality, i.e. those in the eastern and Baltic regions, also tend to have higher average rates of mortality. As a result, the range of variation of absolute inequalities in mortality is even larger than that seen for relative inequalities, suggesting an enormous scope for reducing inequalities in mortality (Mackenbach et al. 2016). While the mortality rates of the higher educated are rather similar in different countries, the mortality rates of the lower educated are much more variable, and higher in countries with larger inequalities in mortality. In other words, the mortality rates among the lower educated drive the magnitude of inequalities in mortality in a country, suggesting that the lower educated are more vulnerable to unfavourable national conditions (van Raalte et al. 2011).

Cause-specific mortality

Across Europe, rates of mortality from ischaemic heart diseases (IHD) are higher among lower as compared to higher socioeconomic groups (Kulhanova et al. 2016). The highest mortality rates in the lowest educational group are observed in the eastern European countries included. In fact, eastern European countries with high inequalities in IHD mortality rates show higher mortality rates in all educational groups. Unfavourable material circumstances, lack of control over life circumstances, and (a culture that approves) hazardous drinking seem to have affected health of the entire population, and those in the lowest education groups specifically (Mackenbach et al. 2008). Southern European countries never witnessed an ‘epidemic’ of IHD mortality, and inequalities in IHD mortality have not arisen.

Consistently higher mortality rates among those in lower as compared to higher socioeconomic groups are also found for stroke. Again, eastern European countries show above-average absolute inequalities in stroke mortality (Mackenbach et al. 2016). Although absolute mortality rates are substantially lower among women, higher absolute inequalities in stroke mortality are found in women in eastern European countries as well (Mackenbach et al. 2008).

Inequalities in mortality from cancer are often large among men, partly because of the excess lung cancer mortality in lower socioeconomic groups (Van der Heyden et al. 2009). Inequalities in cancer mortality are often smaller in women; sometimes they are really small or even have a ‘reverse’ direction, with higher mortality among the higher educated, particularly in Southern Europe (Mackenbach et al. 2008). This is because lung cancer mortality does not (yet) have the same negative association with SES status among women as it has among men, and because the most important cause of cancer mortality among women, breast cancer, often had a ‘positive’ association with SES. However, some evidence suggests a change in the direction of the association, with positive associations no longer being significant (Gadeyne et al. 2017). For lung cancer, there are similar indications for a future change in gradient among women (Van der Heyden et al. 2009).

External causes of injury are another important contributor to socioeconomic inequalities in mortality, particularly (but not exclusively) in Eastern Europe. Mortality from road traffic accidents, from suicides and from homicides is higher in lower socioeconomic groups among men, but not or less clearly so among women (Lorant et al. 2005; Stickley et al. 2012). The larger inequalities in injury mortality in Eastern Europe are likely to be related to higher rates of excessive alcohol consumption (Mackenbach et al. 2008).

Trends

Socioeconomic inequalities in mortality are not a static phenomenon. In addition to the already mentioned change in the direction of the association between SES and breast cancer mortality, this can be illustrated for IHD. In many countries, particularly in the North of Europe, mortality from IHD increased substantially after the Second World War. In the North of Europe, during the 1950s and 1960s IHD mortality was higher in the higher socioeconomic groups, leading to the notion of IHD being a 'manager's disease'. It was only during the 1970s, coinciding with the start of the decline of IHD mortality in the population as a whole, that the current inverse association emerged (Gonzalez et al. 1998).

In the past two decades, absolute declines in all-cause mortality became larger among lower socioeconomic groups, and contributed to the smaller absolute inequalities in mortality in men and women in some North-European countries (Mackenbach et al. 2016). As a result of economic and social developments after political changes around 1990, Eastern European countries witnessed a widening of the gap in death rates (Leinsalu et al. 2009). Recent evidence, however, shows that the initial increase in mortality rates among lower educated men in many countries in Eastern Europe were followed by a decrease around 2008 (Mackenbach et al. 2018).

The latter finding of a decline in mortality among the lower educated across Europe deviates from the situation in the United States. Specifically, mortality rates for white non-Hispanic US 45–54-year-old adults in the lowest educational group increased (Case and Deaton 2015), which has been mainly attributed to increases in mortality from external causes (drug and alcohol poisoning and suicides).

Life expectancy is shorter in lower socioeconomic groups

As a result of these differences in the risk of dying, people from lower socioeconomic groups live considerably shorter lives than those with more advantaged social positions (Stringhini et al. 2017). Again, this difference varies by country. Whereas the difference in life expectancy between primary or lower secondary educated on the one hand and tertiary educated persons on the other hand is relatively small in Italy (2.3 years among men and 0.6 among women), it is large in Lithuania (9.2 years among men and 4.7 among women) (Mäki et al. 2014).

Again, the United States and Europe seem to deviate when it comes to recent trends. A decrease in life expectancy among the lowest educated contributed to an increase in absolute inequalities in life expectancy between 1990 and 2008 in the United States (Olshansky et al. 2012).

Morbidity

Inequalities in generic health indicators

For one indicator, self-assessed health (measured with a single question on an individual's perception of his or her own health), the availability of data is almost as great as that for inequalities in mortality (Fig. 2.4.1).

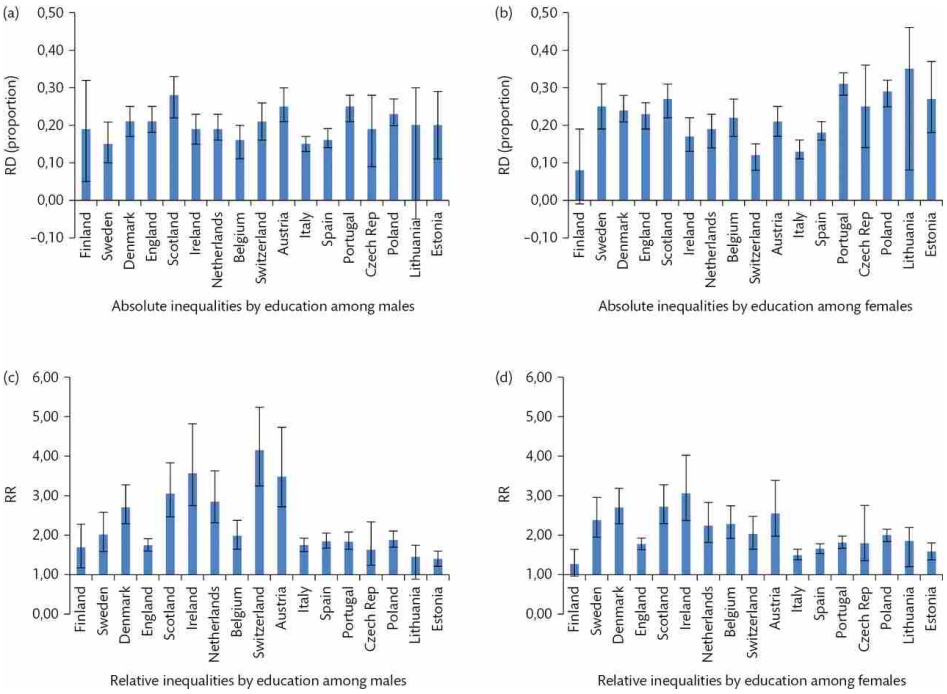

Fig. 2.4.1 Absolute and relative inequalities in self-assessed health across Europe.
Reprinted from Hu, Y. et al. (2016) 'Trends in socioeconomic inequalities in self-assessed health in 17 European countries between 1990 and 2010'. *Journal Epidemiology Community Health* 70: 644–52, with permission from the BMJ Publishing Group Ltd.

The overall pattern is clear again: prevalence rates of less than 'good' self-assessed health are higher in lower socioeconomic groups, resulting in both absolute and relative inequalities (Hu et al. 2016a, b). Although self-assessed health is a good predictor of mortality, trends in inequalities in mortality and in 'less than good' self-assessed health do not correspond exactly. Specifically, whereas absolute inequalities in mortality declined in many countries, they remained rather stable in less than 'good' self-assessed health (Hu et al. 2016a, b).

Inequalities in diseases and disabilities

Socioeconomic inequalities can also be found for many specific indicators, including objective measurements of the incidence or prevalence of diseases and disabilities. Many studies have shown socioeconomic inequalities in the incidence and prevalence of cardiovascular diseases (Manrique-Garcia et al. 2011). Although the size of absolute and relative inequalities seem to differ by diagnosis, substantial inequalities are found for coronary heart diseases, acute myocardial infarction, stroke, and heart failure (Christensen et al. 2016). In addition to a higher incidence, lower socioeconomic groups also tend to have a higher case fatality (Yang et al. 2012).

Similarly, inequalities in cancer mortality reflect inequalities in both incidence and survival. Many cancers, particularly those associated with smoking, excessive alcohol consumption, and other lifestyle factors, such as cancers of the respiratory and upper digestive tract, have a higher incidence in the lower socioeconomic groups, whereas risks of cancer of the prostate, breast, ovary, and colon, and malignant melanoma are often less clear, absent or positive (Aarts et al. 2010). That the prevalence of cancer tends not to be different between socioeconomic groups (Dalstra et al. 2005) is perhaps because longer survival of higher SES patients 'compensates' their lower incidence. Whereas the incidence of breast cancer has been higher for women in higher socioeconomic groups, case fatality rates are higher in lower socioeconomic groups (Lundqvist et al. 2016). Similarly, survival of prostate cancer is lower among patients in lower socioeconomic groups (Klein and Von dem

Knesebeck 2015). As suggested by data on mortality from suicide (see earlier), mental ill health tends to be more prevalent in lower socioeconomic groups (Lorant et al. 2007). The higher prevalence of mental illness in lower socioeconomic groups is likely to have a complex explanation. In psychiatric epidemiology, there is a long tradition of looking at the possible effects of mental health problems on downward social mobility. This 'drift hypothesis' has indeed found some support, for example, in the case of schizophrenia, whose onset usually occurs in adolescence and young adulthood, and which may consequently interfere with school and early work careers. On the other hand, incidence studies have also found higher rates of many mental health problems among those who are currently in a lower socioeconomic position. It seems likely that this at least partly reflects a causal effect, perhaps through a higher exposure to psychosocial stressors and/or a lack of coping resources (Lorant et al. 2007).

As a result of the higher frequency of physical and mental health problems in lower socioeconomic groups, the prevalence of limitations in functioning and various forms of disability also tends to be higher. This applies to many aspects of functioning (mobility, sensory functioning, grip strength, walking speed, etc.) and is particularly evident among the elderly (Stringhini et al. 2018).

'Healthy life expectancy' is shorter in lower socioeconomic groups

The fact that mortality and morbidity rates (among those who are still alive) are higher in lower socioeconomic groups contributes to even larger inequalities in 'healthy life expectancy' (the number of years which people can expect to live in good health). Inequalities in the number of years lived in good health are often seen of more than 10 years (Majer et al. 2011).

The facts: explanation

During the past decades, great progress has been made in unravelling the determinants of health inequalities in high-income countries, and here we will summarize the evidence under three headings: 'selection' versus 'causation', 'specific causal pathways', and 'overarching ideas'.

'Selection' versus 'causation'

Early debates

Selection explanations imply that health determines SES. Because of the occurrence of 'social mobility' (changes in SES during a person's lifetime) there is ample scope for selection processes: health problems may lead to downward social mobility, and upward mobility may be more likely for those with above-average health.

The occurrence of health-related selection is undisputed: during social mobility, some degree of selection on (ill) health does indeed occur, with people who are in poor physical or mental health being more likely to be downwardly mobile (e.g. get a lower status job, or lose income) and less likely to be upwardly mobile (e.g. finish high-level education, or obtain a highly paid job), than people who are in good health. The contribution of health-related selection to the explanation of socioeconomic inequalities in health is small, at least when occupational class or education is used as an indicator of SES (Bartley and Plewis 1997). This is because most health problems occur in late middle or old age, after people have reached their final level of education and main occupational status.

Income, however, is much more sensitive to health status than education or occupational class. For example, poor self-perceived health is an important determinant of transitions into disability pensions, unemployment, and early retirement (Van Rijn et al. 2014), and as such presumably to a

decrease in income. In a study using a more objective indicator of health, employees with an unscheduled hospitalization that could not be postponed experienced a drop in income 2 years later, as compared to matched employees who were not hospitalized. The same absolute reduction in income between the poorest and richest meant that the relative impact of the hospitalization was larger among the poorest (García-Gómez et al. 2013). There is also scope for an impact of what has been called 'indirect selection'—that is, selection on determinants of health. For example, some evidence suggests that obesity affects social mobility, perhaps because of discrimination during recruitment for jobs or promotion (Karnehed et al. 2008).

Selection on the basis of personal attributes, such as cognitive ability, coping styles, control beliefs, personality, and bodily and mental fitness, is also important. These attributes may influence educational and occupational achievement, and at the same time determine later health, either directly or through health-related behaviour. Empirical studies have found associations between many of these personal attributes and social mobility (Lounsbury et al. 2003), and some studies suggest that factors like personality and cognitive ability do indeed contribute to the explanation of health inequalities (Bijwaard et at al. 2015).

Disentangling causal effects

Confounding by both measured and unmeasured variables, and the exclusion of reverse causation are major problems in disentangling the causal impact of SES on health (see Chapter 5.14). Because randomization by SES is not possible, situations have been sought that mimic experimental manipulation (see Chapter 5.10). In lotteries for example, large amounts of money are allocated randomly. Evidence suggests that the impact of winning substantial lottery prizes on mortality, healthcare utilization, and child development outcomes is weak (Cesarini et al. 2016).

Historical changes in the age of compulsory education have been used to study the causal effect of education on mortality. In the United States, between 1915 and 1939, at least 30 states changed their compulsory schooling laws. A comparison of later-life mortality of children attending school just before and just after the changes took effect showed that 1 year of extra schooling reduced mortality substantially (Lleras-Muney 2002). Such results have also been reported for other countries (Kippersluis et al. 2011; Lager and Torssander 2012). A study using state-level school laws and school characteristics to predict years of education, reported that the variation in predicted years of education was inversely related to the risk of dementia (Nguyen et al. 2016). Together, these studies seem to suggest that a causal effect of education is more likely than a causal effect of income and wealth on health outcomes.

Specific causal pathways

The findings summarized in the previous paragraph suggest that socioeconomic inequalities in health at least partly reflect a causal effect of SES on health. The debate on the relative contribution of such causal mechanisms, however, is far from closed. That also applies to the exact nature of these causal mechanisms, which are likely to be largely indirect, by raising the prevalence of specific determinants of morbidity or mortality in lower socioeconomic groups.

Many risk factors for morbidity and mortality are more prevalent in lower socioeconomic groups. Three groups of explanatory factors are likely to explain the bulk of health inequalities in high-income countries: material, psychosocial, and behavioural risk factors (Van Oort et al. 2005). Healthcare may also play a role. Figure 2.4.2 provides a schematic representation of these mechanisms.

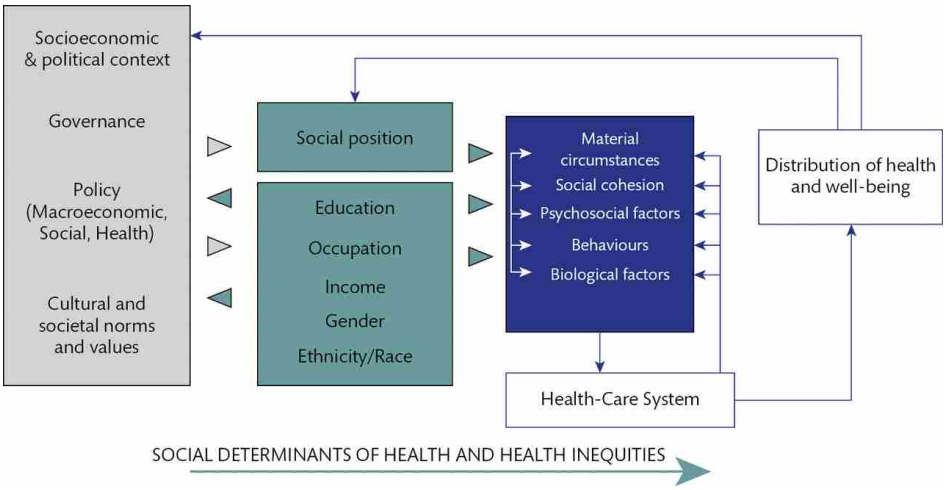

Fig. 2.4.2 A possible model for the explanation of health inequalities.

Material factors

There is no doubt that financial resources and related unfavourable material living conditions are very unevenly distributed between people with a lower and higher SES, even in high-income countries with strong egalitarian traditions. For example, in 2014, the average disposable income of the richest ten percent was about 9.5 times higher than that of the poorest ten percent in Europe (OECD 2017).

Financial disadvantage may affect health through various mechanisms. The lowest possible costs for healthy living (as defined by health-based needs for nutrition, physical activity, housing, medical care, social needs, hygiene, and transport) tend to exceed minimum benefit levels (Morris et al. 2007). Yet, for some health behaviours, the cheapest option is also the healthiest, which is obvious in the case of smoking. That smoking is more prevalent among those in the lowest income groups has been attributed, among other factors, to the stress resulting from living in poor material conditions (Beenackers et al. 2018).

Other ‘material’ risk factors that tend to be more prevalent in lower socioeconomic groups include occupational health risks (exposure to chemicals, accident risks, physically strenuous work, etc.) (Costa and D’Errico 2006), health risks related to housing (crowding, dampness, accident risks, etc.) (Dunn and Hayes 1999), and environmental health risks (air pollution, traffic noise, etc.) (Kruize et al. 2007). Some of these factors have been shown to make important contributions to the explanation of health inequalities (Marmot and Wilkinson 2006).

Psychosocial factors

The second group of specific determinants which contribute to the explanation of health inequalities are psychosocial factors. Those with a low SES on average are exposed to more psychosocial stressors, in the form of negative life events, daily hassles, an ‘effort–reward imbalance’ (high levels of effort without appropriate material and immaterial rewards), and a combination of high demands and low control both in the workplace and beyond (Siegrist and Marmot 2004).

At the same time, they also tend to have lower levels of social support (Stansfeld 2006), as well as less effective coping styles (Kristenson 2006) and a weaker sense of control over their life and living conditions (Bosma et al. 1999). This combination of a higher exposure to psychosocial stressors and

less capacity to remove or buffer these exposures may explain part of the higher frequency of health problems in the lower socioeconomic groups. This has been best documented for psychosocial factors related to work organization, such as job strain, which have been shown to play a role in the explanation of socioeconomic inequalities in cardiovascular health (Marmot et al. 2006).

Two possible pathways may be involved. According to the increasingly popular 'scarcity-theory' (Mullainathan et al. 2013) stress from exposure to poor material circumstances (such as financial stress) limits individuals' 'cognitive bandwidth', probably leading to less self-control and ultimately unhealthy behaviour (Beenackers et al. 2018). The second is a biological pathway. The experience of stress affects the neural, endocrine, and immune systems of the body, and chronic stress may lead to maladaptive responses in the form of, for example, high blood pressure, a prolonged high level of cortisol, higher blood viscosity, or a suppression of the immune response, which may in their turn increase the susceptibility to a range of diseases (Brunner 2017). In this context, studies also refer to the concept of 'allostatic load', e.g. the cumulative physiological burden of exposure to stressful circumstances (the bodies' 'wear and tear'). Socioeconomic inequalities in cardiovascular, metabolic, and inflammatory markers used to measure allostatic load, have been explained by stressful living conditions (Robertson et al. 2015), and as such provide an explanation how unfavourable material and psychosocial factors 'get under skin'.

Health-related behaviours

The third group of contributory factors are health-related behaviours, such as smoking, inadequate diet, excessive alcohol consumption, and lack of physical exercise (Oude Groeniger et al. 2016, 2017). In many developed countries one or more of these 'lifestyle' factors are more prevalent in the lower socioeconomic groups. As we have already seen, many of the disease-specific patterns of health inequalities also suggest a substantial contribution of health-related behaviours to inequalities in mortality.

By far the most widely available data on a specific determinant of health inequalities relate to smoking. The prevalence of smoking differs strongly between socioeconomic groups in many European countries (although variations in the magnitude of these inequalities between countries have been reported), so one can safely assume that it plays an important role in generating health inequalities (Huisman et al. 2005). The prevalence of smoking has declined over the past decades in many countries, at least among men. In the first decade of this century, the proportion of quitters among ever-smokers was higher among those in higher than in lower socioeconomic groups, leading to a widening of relative inequalities in smoking (Bosdriesz et al. 2015).

Socioeconomic inequalities in alcohol-attributed mortality suggest an important contribution of excessive alcohol consumption to inequalities in mortality (Probst et al. 2014), particularly in Eastern Europe (Mackenbach et al. 2015a). Indeed, excessive alcohol consumption is more frequent among those with a lower SES, and increases mortality risks (Woods et al. 2018). Alcohol, however, is a complex factor in this context: abstinence, which is more frequent in lower socioeconomic groups, is often associated with a higher mortality risk, as compared to light alcohol consumption in observational epidemiological research (Woods et al. 2018). Moderate alcohol consumption is more frequent in higher socioeconomic groups, and often associated with a lower risk of cardiovascular disease mortality (Ronksley et al. 2011). Methodologically stronger evidence, however, challenges the protective effect of light-to-moderate as compared to non-drinking, and suggests that a lower mortality risk results from residual confounding by for example factors directly related to SES (Holmes et al. 2014).

Socioeconomic inequalities in diet, particularly in fruit and vegetable consumption and fat intake, are well-established (Giskes et al. 2010). Only a few comparative studies have been conducted, and these show that men and women in lower socioeconomic groups tend to less frequently eat fresh vegetables, particularly in the North of Europe. Literature reviews have shown that it is likely that

many other aspects of diet, such as consumption of meat, dairy products, and various fats and oils, also are socially patterned in many European countries, and that these social patterns differ between countries (Lopez-Azpiazu et al. 2003).

Socioeconomic patterns in physical activity depend on the type of activity. A lack of leisure-time physical activity tends to be more common in the lower socioeconomic groups, whereas occupational physical activity is less common among higher socioeconomic groups (Beenackers et al. 2012). High levels of occupational physical activity, however, are related to early mortality (Coenen et al. 2018) and as such may contribute to socioeconomic inequalities in mortality.

A lack of physical activity and an unhealthy diet are the main determinants of obesity. The increase in the prevalence of obesity over the past decades is, beyond doubt, among the major challenges in public health. Interestingly, this is one of the very few health aspects where patterns of social variation are clearer for women than for men. Among women, overweight and obesity are more prevalent in lower socioeconomic groups in European countries with available data, with clearly large inequalities in overweight and obesity in Southern Europe (Roskam et al. 2010). Recent evidence suggests a widening of absolute inequalities in obesity in many countries in Europe, but not of relative inequalities, both among men and women (Hoffmann et al. 2017).

The systematic nature of these differences in health-related behaviour clearly demonstrates that these are not a matter of free choice. While there is evidence of socioeconomic inequalities in intrapersonal determinants of behavioural changes, such as attitudes towards health behaviour (Kamphuis et al. 2009), such findings still do not provide an answer to the question why these determinants are socioeconomically patterned. As a result, the attention shifted towards the role of physical and sociocultural environmental conditions which are at least partly beyond the control of the individual (Van Lenthe et al. 2005).

With regard to the physical ('built') environment, empirical evidence testing the 'deprivation amplification' hypothesis, according to which lower socioeconomic groups are exposed to contextual disadvantages in terms of the availability and accessibility of health enhancing facilities and healthy products produced inconsistent findings, at least in many European countries (Macintyre 2007). There are indications that built environmental characteristics play a more important role in the United States, suggesting again that macro-level processes leading to socioeconomic patterning of these characteristics are involved in generating the inequalities (Cummins and Macintyre 2006). Overall however, there remains an important knowledge gap if and how built environments contribute to inequalities in health behaviour.

With regard to the sociocultural environment, evidence suggests that social capital and social resources, such as membership of support-providing networks and perceived social support, are associated with health behaviour (Conklin et al. 2014). Their contribution to socioeconomic inequalities in health behaviour is less clear. Scholars also explored the role of 'cultural capital', e.g. culture-based resources that shape and influence people's habits, values, norms, knowledge, and preferences, and that are acquired mostly through social learning, with learning conditions varying between socioeconomic groups and milieus (Bourdieu 1984). Bourdieu argued that food and sport preferences may become part of an identity and can be used as a distinction mechanism between social groups. Emerging evidence suggests that cultural capital is a promising explanation for socioeconomic inequalities in healthy behaviour (Oude Groeniger et al. 2017).

Healthcare

Unequal access to effective healthcare could theoretically also play a role in the explanation of health inequalities. Most high-income countries, however, have healthcare financing systems that have reduced inequalities in access to rather low levels. This is clear from studies of healthcare utilization, which typically show that lower socioeconomic groups tend to use more care than higher socioeconomic groups in accordance with their higher levels of need, and that relatively low use of

specialist care in lower socioeconomic groups goes together with relatively high use of primary care (van Doorslaer et al. 2006).

Studies of variations in healthcare outcomes do suggest that there may be inequalities in quality of care that are not captured by studies of global indicators of healthcare utilization. As was mentioned earlier, survival after a cardiovascular event or after a diagnosis of cancer is often shorter for patients in lower socioeconomic groups. Some studies have found higher rates of utilization of surgical and non-surgical interventions among hospitalized patients with a higher socioeconomic position (Stirbu et al. 2012). Like inequalities in survival after myocardial infarction, inequalities in survival of cancer patients are likely to be partly determined by inequalities in comorbidity or other risk factors for mortality independent of care received, but there is some emerging evidence that inequalities in treatment may also play a role, for example, in the case of breast cancer (Aarts et al. 2012).

At the population level, mortality from causes of death that have become amenable to medical intervention also is higher in lower socioeconomic groups. Inequalities in mortality from these conditions are often substantial, and contribute between 11 and 24% to inequalities in partial life expectancy between the ages of 30 and 64 (Stirbu et al. 2010). To what extent these inequalities really reflect inequalities in healthcare access or quality is, however, uncertain. Countries with larger inequalities in healthcare utilization have not been found to also have larger inequalities in amenable mortality (Plug et al. 2012).

A role for genes?

In intriguing question is whether genes contribute to health inequalities. Genetic factors do not easily fit into ‘causation’-type explanations, because temporally a person’s genotype precedes his/her SES, and a causal effect of the latter on the first is therefore logically impossible (Mackenbach 2005). In fact, genes which are both more frequent in lower than in higher socioeconomic groups and predispose to health, would confound the association between SES and health outcomes. This situation is not entirely unlikely: genes may be more frequent in lower socioeconomic groups when they predispose to health outcomes, which subsequently lead to social mobility. For example, genes may predispose to personal attributes such as cognitive ability or personality traits, which may lead to downward social mobility and may affect health. A ‘contribution’ of genes to health inequalities may however, come from ‘gene-environment’ interactions, whereby the health (dis)advantages of higher and lower socioeconomic groups differ between those with different genes. SES may also change gene functioning (e.g. the process of DNA methylation) in absence of changes in DNA sequences (‘epigenetics’), and as such contribute to health inequalities (Fiorito et al. 2017).

Overarching ideas

What has emerged from recent research efforts is a rather complex picture of how individuals in the lower socioeconomic strata are exposed over their lifetime to a wide variety of unfavourable and interacting material, cultural, and psychological conditions, and how these exposures lead to ill health —either directly, or indirectly through unhealthy behaviours or psychosocial stress. Various attempts have been made to combine these factors and pathways into overarching theories. We discuss some of these attempts in the following sections.

Life course perspective

In a life course perspective, health, or disease risk in lower socioeconomic groups later in life result from socially patterned exposures during gestation, childhood, adolescence, young adulthood, and later adult life (see Chapter 5.20). Different life course models have been developed, of which the ‘critical period’ model and the ‘accumulation’ model are most prominent.

In a critical period model, SES has an exclusive effect on health in later life in a short and specific period in life, but not in other periods of life (Mishra et al. 2013). One example of a 'critical period' model relates to the 'developmental origins of health and disease' hypothesis. According to this hypothesis a low birth weight is not only associated with infant health, but also with adult health, e.g. coronary heart disease, stroke, hypertension, and diabetes, probably due to 'fetal programming' of growth patterns and related metabolic and endocrine processes (Barker and Robinson 1992). Robust evidence exists of socioeconomic inequalities in unfavourable birth outcomes, including a low birth weight, preterm birth, babies born small for gestational age (Blumenshine et al. 2010). To the extent that fetal programming results in persistent and structural changes, a low socioeconomic status in pregnancy can be seen as a critical period.

According to the accumulation model, different forms of material and immaterial disadvantage tend to cluster in the same persons, either uncorrelated or with one disadvantage increasing the likelihood of another one at a later point in time. Empirically, accumulation is often tested by investigating dose–response relationships between socioeconomic status at different periods in life and health outcomes in later life (Pollitt et al. 2005). Indeed, risk of disease and mortality increases with an increase in exposure to a low socioeconomic status during life (Mishra et al. 2013).

Accumulation models can be refined to take into account chains of events reinforcing each other. Interestingly, this also resolves the 'selection' versus 'causation' debate, because a low socioeconomic status in one stage of the life course may translate into a health disadvantage in the next, which may then lead to a still lower socioeconomic status some years later, and so on. Health-induced downward social mobility then becomes just another form of accumulation of disadvantage.

Clearly, the implicit assumption in accumulation models of an equally strong impact of socioeconomic status at different periods of life may be invalid. In a 'sensitive period' model exposure to a low socioeconomic status at different periods in life exerts different effects on health in later life. Although disentangling life course models empirically is complex, evidence suggests that a sensitive period model, in which a low socioeconomic status later in life is more strongly related to mortality than a low socioeconomic status earlier in life, best describes the effect of socioeconomic status in mortality across the life course (Mishra et al. 2013).

Fundamental causes

The theory of 'fundamental causes' stipulates that it is the social forces underlying social stratification which ultimately cause health inequalities, and not exposure to the proximal risk factors which are usually studied by social epidemiologists (like smoking, psychosocial stress, working conditions, etc.). According to this theory, the persistence of health inequalities in different time-periods and different national conditions is due to the fact that a person's socioeconomic status provides him or her with 'flexible resources'. These include 'knowledge, money, power, prestige, and beneficial social connections' which can be used 'to avoid disease risks or to minimize the consequences of disease once it occurs' regardless of the prevailing circumstances. The association between SES and health 'is reproduced over time via the replacement of intervening mechanisms', and as opportunities for avoiding disease continue to expand so will health inequalities continue to exist (Phelan et al. 2010).

This theory provides an elegant summary of all the more specific explanations, which fail to explain why health inequalities are seen in all countries with available data, and persist over time, regardless of variations in the proximal determinants of health. Existing empirical tests tend to be in line with the theory (Mackenbach et al. 2015b), Yet, how additional resources of higher socioeconomic groups do protect against prevailing health risk needs further exploration (Mackenbach et al. 2017). The theory is, however, a useful reminder that in the end the existence of health inequalities depends on the existence of socioeconomic inequalities.

Health inequalities and the welfare state

The persistence of socioeconomic inequalities in health is one of the great disappointments of public health. All countries, including those ranking high on indices of economic prosperity and human development, have systematic inequalities in mortality and morbidity between citizens with a higher and a lower socioeconomic position, as indicated by education, occupation, income, or wealth. This also applies to the highly developed 'welfare states' of Western Europe. All Western European countries have created extensive arrangements aiming to reduce socioeconomic inequality and its various consequences. With notable variations all these 'welfare regimes' include measures to redistribute income (e.g. by progressive taxation and social security) and a range of collectively financed provisions (e.g. public housing, education, healthcare, access to culture and leisure facilities) (Esping-Andersen 1990).

There is good evidence that welfare policies have contributed to a reduction of inequalities in income, housing quality, healthcare access, and other social and economic outcomes (Kautto et al. 2001), but they have apparently been insufficient to eliminate health inequalities. The explanation of this paradox has puzzled observers (Bambra 2011), and several hypotheses have emerged. Three circumstances may help to explain the persistence of health inequalities despite attenuation of inequalities in material conditions by the welfare state: (1) inequalities in access to material and immaterial resources have not been eliminated by the welfare state, and are still substantial; (2) due to greater intergenerational mobility, the composition of lower socioeconomic groups has become more homogeneous with regard to personal characteristics associated with ill health; and (3) due to a change in epidemiological regime, in which consumption behaviour became the most important determinant of ill health, the marginal benefits of the immaterial resources to which a higher social position gives access have increased (Mackenbach 2012).

The options: how to build a strategy to reduce inequalities in health?

With all these advances in our understanding of health inequalities, we are now in a much better position than, say, in 1980 when the Black Report appeared (Department of Health and Social Services 1980), to develop rational strategies to tackle them. Bringing together evidence from around the world, the World Health Organization has called upon all countries to 'close the gap in a generation' (Commission on Social Determinants of Health 2008).

Normative assessment of health inequalities

Reducing inequalities in health, by levelling up the health status of those in lower socioeconomic positions, has thus become an important policy goal in many high-income countries. One reason is technical: potential health gains are larger in lower socioeconomic groups, and raising their health status may therefore be a very effective way to improve average population health. Another reason is normative: health inequalities are widely perceived to be 'unjust'. One particularly striking illustration of this perception can be found in the report of the WHO Commission on Social Determinants of Health, which stated that '[p]utting right these inequities is a matter of social justice. Reducing health inequities is an ethical imperative. Social injustice is killing people on a grand scale' (Commission on Social Determinants of Health 2008).

It is important, however, to outline the reasoning behind this move from 'inequalities' (a term with ethically neutral connotations, like 'disparities' or 'variations') to 'inequities' (a term which implies that these variations are 'unjust'). This was first done by Whitehead in a simple but effective scheme consisting of two criteria: 'avoidability' (are health inequalities caused by changeable social

conditions, and therefore unnecessary?) and ‘unfairness’ (do health inequalities result from conditions out of people’s direct control, not from free choice?) (Whitehead 1992).

According to these criteria, health inequalities caused by exposure to health hazards in the environment, or by restricted access to healthcare, would be considered unjust, as would health inequalities caused by health-damaging behaviour restricted by socioeconomic factors. On the other hand, health inequalities caused by natural biological variation (e.g. genetic factors) or freely chosen health-damaging behaviour would not (Whitehead 1992). Application of this scheme thus requires empirical evidence on the determinants of health inequalities, and on the role of free choice versus ‘conditions out of people’s direct control’—evidence that is actually hard to obtain, although it is hard to imagine that systematic differences in behaviour between socioeconomic groups are based on truly free choice.

Attempts to further formalize the normative assessment of health inequalities have tried to use Rawls’s influential ‘theory of justice’ (Daniels et al. 1999) or Sen’s capability theory (Venkatapuram 2011). The latter theory has become especially popular among social epidemiologists because, in contrast to other theories of justice, it gives a central place to health. It argues that all human beings are entitled to a certain set of ‘capabilities’, such as the ability to live a life of normal length, to have good health, to have emotional attachments to others, and to participate effectively in political decisions. From this perspective, tackling health inequalities should be a central objective of all governments pursuing justice (Venkatapuram 2011).

Policy development vis-à-vis health inequalities

In reality, different countries are in widely different phases of awareness of, and willingness to take action on, socioeconomic inequalities in health. Common milestones in policy development are: high-profile independent reports recommending research or policy on health inequalities; national research programmes on health inequalities; government advisory committees recommending policies to reduce health inequalities; and coordinated government action to reduce health inequalities (Mackenbach and Bakker 2003).

Whitehead has proposed a schematic ‘action spectrum’ to characterize the stage of diffusion of ideas on socioeconomic inequalities in health (Fig. 2.4.3). Starting with a primordial stage in which socioeconomic inequalities in health are not even measured, the spectrum covers the stages of ‘measurement’, ‘recognition’, ‘awareness’, ‘denial/indifference’, ‘concern’, ‘will to take action’, ‘isolated initiatives’, ‘more structured developments’, and ‘comprehensive coordinated policy’ (Whitehead 1998).

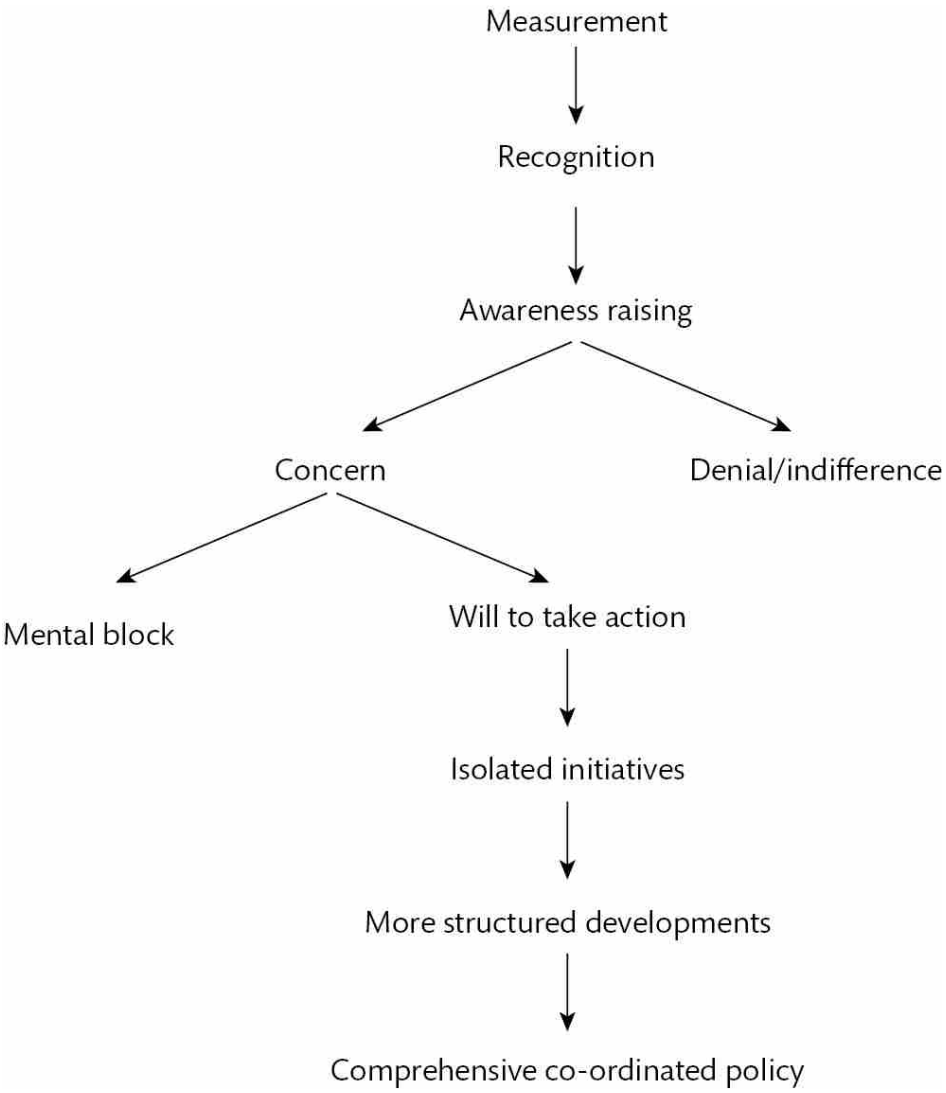

Fig. 2.4.3 Whitehead's action spectrum.
Reproduced from Whitehead, M., Diffusion of ideas on social inequalities in health: a European perspective, *Milbank Quarterly*, Volume 76, Issue 3, pp. 469–92, Copyright © 1998 Milbank Memorial Fund, with permission from John Wiley & Sons, Inc.

Some countries entered a 'more structured developments' stage, with national research programmes as well as high-level advisory committees that have issued comprehensive policy advice on how to reduce socioeconomic inequalities in health, and fewer have started a 'comprehensive coordinated policy' (Whitehead 1998; Mackenbach and Bakker 2003). A rational approach to tackling health inequalities should be based on logical reasoning: dependent on the causes of the problem, and on what is known about possible ways to address these causes, interventions and policies should be developed and tested for effectiveness, and then implemented systematically on the scale required to have population-wide impacts (Whitehead 2007). A possible typology of actions to tackle health inequalities is: (1) strengthening individuals (e.g. improving individuals' abilities to make healthy lifestyle choices); (2) strengthening communities (e.g. community development initiatives to create healthier conditions in neighbourhoods); (3) improving living and working conditions (e.g. improve access to adequate housing and eliminate work-related health risks); and (4) promoting healthy macropolicies (e.g. reduce income inequalities) (Whitehead 2007).

Within high-income countries, there is considerable diversity in the way scientific evidence is being used to underpin policies to reduce health inequalities. Often, most of the evidence used relates to the contribution of specific factors to the explanation of health inequalities, not to the effectiveness of policies and interventions tackling them (Macintyre et al. 2001). It is only rarely that strategies are developed primarily on the basis of evaluation studies of various intervention options (Mackenbach and Stronks 2004). As we will see in the next section the evidence base is still very limited, and opinions differ on what type of evidence is needed to underpin policies and interventions in this field.

There are those who argue that in view of the urgency of starting to tackle health inequalities ('doing nothing is not an option') (Petticrew et al. 2004), one should be prepared to start intervening on the basis of plausibility. Political 'windows of opportunity' are usually short, for example, 4 years at most, and they may be closed before careful evaluation studies have been conducted (Whitehead et al. 2004). A parallel has been drawn with nineteenth-century public health interventions for which controlled intervention studies have never been done, but which were implemented on the basis of plausibility and have proven to be highly successful (Davey Smith et al. 2001). Under the pressure of politicians wanting to see rapid results, the best that can be achieved in terms of scientific evaluation may then be large-scale implementation accompanied by a 'real-time' evaluation study of the intervention, concurrent with its implementation, using some quasi-experimental design (before–after study, interrupted time-series study, and so on) (Macintyre 2003).

On the other hand, there are those who argue that this is a strategy with serious risks. Like in other areas of social and health policy, the actual results of policies and interventions to reduce health inequalities could easily be counterintuitive. There are many historical examples of 'plausible' interventions and policies that did not work, or actually had adverse effects (Macintyre et al. 2001). In addition to that, one could argue that any investment in reducing health inequalities should be justified on the basis of a comparison of its cost-effectiveness with that of other possible investments in health and well-being, and that producing credible evidence is therefore essential (Oliver 2010).

Another issue for debate is what types of evidence are best suited to underpin policy decisions in this area. Clearly, randomized controlled trials will not always be feasible, particularly for the evaluation of policies and interventions that are applied on a population-wide scale. Sometimes, community intervention trials, in which groups of people (school classes, neighbourhoods, etc.) instead of individuals are allocated to the intervention and control condition, will then be a good alternative. But in many circumstances one will have to rely on quasi-experimental or even observational designs to inform policymakers on the effectiveness of new approaches. Controlled before–after studies or interrupted time-series designs could then be used, or observational studies of 'natural experiments', for example, by making comparisons between countries (Thomson et al. 2004). Useful guidance has been developed to support further research in this area (Craig et al. 2011), including the application of techniques applied in economics and econometrics (Hu et al. 2017). Also, a Cochrane and Campbell Equity Methods group has been set up to ensure that research about differential effectiveness of health interventions is available worldwide (http://equity.cochrane.org/).

A complicating factor in evaluating the effectiveness of policies and interventions to reduce health inequalities is that this effectiveness should be measured in terms of favourably changing the distribution of health problems in the population, not of reducing the rate of health problems in a particular group. A 'full' study design therefore requires the measurement, in one or more experimental populations and one or more control populations, of changes over time in the magnitude of health inequalities. Any other design, such as an experimental study of changes over time in the rate of health problems in lower socioeconomic groups only, requires rather strong assumptions to be made, in this case on the absence of health effects in higher socioeconomic groups (Mackenbach and Gunning-Schepers 1997).

Approaches to reduce health inequalities

A number of approaches to reduce health inequalities have been developed, for which there is at least some empirical evidence suggesting that they can help to reduce health inequalities.

In general, there seems to be an 'inverse evidence law', in the sense that more is known about small-scale interventions with potentially little population-level impact, and less is known about interventions and policies with a potentially large impact (Nutbeam 2003). A few promising approaches using different entry-points, are discussed here.

Governmental (social) policies at the national and local level affect education, income, and related material living conditions. If such policies effectively improve the conditions for those in lower socioeconomic groups specifically, and (as a result) lead to improvements in health, health inequalities will be reduced. For example, the United Kingdom introduced a national minimum wage in 1999, resulting in an increase of the lowest incomes. A comparison of those exposed to this increase with a group who earned just more than the minimum wage before and after the introduction or those who experienced no increase, revealed a significant improvement in mental health, but not in health behaviour, in the 'intervention' group (Reeves et al. 2017). Despite the potential to tackle health inequalities via social interventions covering housing, work, transport, unemployment, food, and education, a differential impact on socioeconomic groups is only occasionally studied. To the extent it has been done, work interventions showed some evidence for an effect on reducing inequalities (Bambra et al. 2010).

The important contribution of health behaviour to health inequalities makes health promotion among lower socioeconomic groups a potentially effective approach. One way to classify interventions for this purpose is to assess the degree of choice for individuals, resulting in 'structural' interventions (in which individual choice is removed), 'agento-structural' interventions and 'agentic' interventions (in which individuals are required to make independent choices) (Backholer et al. 2014). Of these, structural interventions seem to be best able to reduce inequalities in health behaviour. Fiscal policies are a good example of a structural intervention with a potentially larger impact on lower than higher socioeconomic groups. Indeed, the effects of raising taxes on tobacco is effective in reducing smoking among lower socioeconomic groups particularly (Main et al. 2008). Recent evidence suggests that a tax on sugar-sweetened beverages is either equally effective across socioeconomic groups or more effective among lower socioeconomic groups (Backholer et al. 2016). Such policies, however, are sometimes criticized for their regressive nature, meaning that the same tax takes a proportionally larger part of lower than higher incomes. One potential way to overcome this criticism is to use these tax revenues for public health investments for the lowest socioeconomic groups. Instead of taxing unhealthy products, there are also indications that lowering costs for healthy products contributes to a reduction of inequalities in health behaviour. A Norwegian experiment showed a large change in the uptake of fruits and a larger decline in the consumption of unhealthy snacks after the introduction of free fruit at schools (Øverby et al. 2012).

Agento-structural interventions target both environmental and individual conditions. They can be implemented in neighbourhoods, but also in schools or workplaces. While the evidence of a reduction of inequalities in health behaviour is not overwhelming, this type of project does have more potential than single interventions. Indeed, an equity specific re-analysis of obesity-related lifestyle interventions showed that intensive and long-lasting community-based projects are potentially able to reduce inequalities in health behaviour (Magnée et al. 2013).

Agentic interventions, entirely relying on individual choice, run the risk of widening instead of closing the gap between socioeconomic groups. This is perhaps, because the cognitive resources needed to fully benefit from these interventions are more prevalent among the higher educated (Magnée et al. 2013).

Comprehensive strategies: evidence from the English strategy

The Black Report, commissioned by a Labour government to investigate the causes and possible remedies for Britain's undiminished social class inequalities in mortality, had proposed a radical change in social and healthcare policies but disappeared into a desk drawer after the Conservatives won the 1979 elections (Department of Health and Social Services 1980). However, research continued and when Labour came back into power almost 20 years later, it again commissioned an expert report to bring together all the evidence—the Independent Inquiry into Inequalities in Health (Department of Health 1998)—and developed a comprehensive programme to tackle health inequalities.

This programme consisted of a range of new government policies including the introduction of a national minimum wage, higher benefits, and pensions, and substantially increased spending on education, housing, urban regeneration, and healthcare. It also announced a number of specific initiatives including the 'Sure Start' programme (free child care, early education, and parent support for low-income families), 'Health Action Zones' (local strategies to improve health in deprived areas), and a series of antitobacco policies (including free nicotine replacement therapy for low-income smokers) (Department of Health 1999). In a further evolution of the programme two quantitative targets (to narrow the socioeconomic gap in life expectancy and that in infant mortality by 10% in 2010) were added, and priority was given to key interventions expected to contribute to closing the life expectancy gap, such as reducing smoking in manual social groups, managing risks for coronary heart disease and cancer (poor diet and obesity, physical inactivity, hypertension), and reducing accidents at home and on the road (Department of Health 2003). The total budget exceeded £20 billion (Table 2.4.2).

The strategy came to an end with the 2010 parliamentary elections and the formation of a Conservative/Liberal Democrat coalition government. An extensive review of the achievements of the programme showed that it had been a mixed success: despite positive effects in some areas (e.g. reduction of child poverty, improvements in housing, better uptake of influenza vaccination) most indicators showed a widening instead of a narrowing of health inequalities, and the programme missed its targets (Department of Health 2010). Further analyses showed that the failure to achieve the targets was due to the fact that the strategy had not sufficiently focused on the most relevant entry-points, that effective policies were unavailable at that point in time, and that the scale of implementation had not been sufficient for achieving population-wide impacts (Mackenbach 2011).

Table 2.4.2 The English programme to tackle health inequalities: commitments and their achievement

'Departmental commitments'	Examples	Budget (2004–2007)[a]	Direct relevance for life expectancy target	Direct relevance for infant-mortality target	Commitments mostly met (2007)[b]
Maternal and child health	Sure Start, chikcare, Welfare Food Scheme	>£2 billion	No	Yes	Yes
Improving life chances for children	Mental health, sports facilities, education	>£2 billion	No	No	Yes
Reducing teenage pregnancy	Sex education, care access	Not specified	No	Yes	Yes
Engaging communities	Neighbourhood Renewal, homelessness reduction	>£1.5 billion	No	No	Yes
Prevention	Smoking cessation, 5 A Day, injury prevention	Not specified	Yes	No	Yes
Primary care	Facilities, breast cancer screening, flu immunization	>£1 billion	Yes	No	Yes
Effective treatment	Access to cancer services, access to coronary heart disease services	>£0.5 billion	No	No	Yes
Underlying determinants	Child poverty, fuel poverty, Pathways to Work	>£15.5 billion	No	No	Yes

[a] '>' sign indicates that amounts exclude commitments for which no budget was specified.

These findings were confirmed by a recent analysis, showing that trends in health inequalities did not differ before and after the implementation of the strategy. For most health indicators, changes in trends of health inequalities after 2000 in England were also not significantly different from those seen in Finland, the Netherlands and Italy (Hu et al., 2016a).

Conclusion

Whether it will actually be possible to substantially reduce socioeconomic inequalities in health remains an open question. The good news, however, is that there has been enormous progress in explanatory research, and that this has identified a large number of targets for policies and interventions to tackle health inequalities. There has also been a beginning of research and development for effective interventions and policies to tackle health inequalities. While this is still a modest beginning, it does put us in a better position to reduce socioeconomic inequalities in health in the coming decades. A number of innovative approaches have been developed for which there is at least some evidence of effectiveness. Comprehensive packages have been developed in several countries that have a sound theoretical basis and clear inspirational value.

Developing effective strategies to reduce health inequalities is a daunting task. No single country has the capacity to contribute more than a fraction of the necessary knowledge. This is a matter not only of restricted manpower or financial resources for research, but also of restricted opportunities for implementing and evaluating policies and interventions. Some policies can be implemented and

evaluated in some countries and not in others, either because they have already been implemented or because they are politically infeasible. International exchange is therefore necessary to increase learning speed.

Reducing health inequalities in developing countries

Romulo Paes-Sousa, Paulo M. Buss, and Mauricio L. Barreto

Introduction

Human society is divided into a number of characteristics. Many of these divisions are the result of adaptive, biological, or geographical processes, and others are created in the course of historical, social, economic, or cultural processes. Some of these could be merely differences (e.g. men and women), others are purely social or historical as with the social classes. The importance is that inequalities very often are upgraded to inequities as they define relationships that are essentially based on power and the access to, and the possession of, goods, services, and wealth. Consequently, the fruits of the societal efforts accumulated over generations are unequally distributed (General Assembly 2000; UNDESA 2018). The more visible face of inequality is the existence of people with different level of access to the wealth, and this was observed in all four country income groups—high, upper-middle, lower-middle, and low.

However, an important difference is that social inequalities in both low- and lower-middle-income countries are very often associated with a high level of poverty. While different, there is some overlapping in these two concepts and its consequences and both inequality and poverty has been given very high importance in the study of the social determinants of health. While social inequalities and poverty are both in general higher in lower-middle-income countries when compared with high-income countries, the health literature has in westernized, rich countries emphasized the study of inequalities and health, and the study of poverty and health has great emphasis in lower-middle-income countries. Therefore, while there is an accumulated body of evidence that inequality and poverty have isolated effects on health, in lower-middle-income countries less is known on the

effect of inequalities on health and yet less on the joining effect of inequalities and poverty (UN General Assembly 2000a, b, 2015).

Poverty is an absolute term that defines the lack of resources necessary to have a decent way of life. Certainly, the necessary resource to achieve a decent life vary in time and across different societies. Then, despite the effort to have universal definitions and measures of poverty making easier comparisons among nations, it is in fact very much contextual. In the effort for universal measure, the World Bank uses cut-off values corrected by purchasing power parity-PPP and defines extreme poverty as living on less than US$1.90 per day per capita, and moderate poverty as less than $3.10 a day per capita. In another aspect, inequality is a relational concept related with the distribution of the societal wealth among its members. A commonly used measure of inequality in the GINI Index (GI) that vary from 0 (zero) to 1 (one), where 0 is the situation where the wealth is equally distributed among all members (situation that maybe existed in very primitive societies) and 1 is the maximum of concentration where a member accumulated all the wealth. In present times, HICs with more fair societies have GI below or around 0.3, while the low- and middle-income countries (LMICs) are very often above 0.4 or 0.5, but a few arrive at 0.6 or above. A country can be poorer but less unequal, for instance, India has great poverty than Brazil, but it is less unequal. In 2011, the World Bank estimated 0.549 as the GINI Index of Brazil and 0.341 to India 34.1, while the prevalence of extreme poverty (% of the population living below US$ 1.9/day) was 11.1% and 21.1% in Brazil and India, respectively (UN General Assembly 2012).

As you can see, inequalities within a country relate to the distribution of the accumulated wealth (World Bank, 2018). But, the consolidation of that situation and to transform inequalities in inequities, is dependent on how that society is politically organized and the power and social relations established among its various strata. It is defined by the political organization historically moulded in each society, and how the state redistributed the nation wealth through fiscal and transfer systems, generating greater or lesser distributive distances between existing social groups. Cultural elements are also important regarding amplifying and consolidating some existing inequalities. Inequalities consolidated in the social realm are often visible and sometimes enhanced when the object of study is health, meaning the health conditions or the access to the health services and resources reflect the way the wealth is distributed in that

specific society or nation. Health inequalities generate different chances of exposure to the factors that determine health and disease, different chances about illness and death, as well as unequal possibilities about the ability to take advantage of scientific and technological advances for health. In the same way that social inequalities have persisted in all countries, regardless of their level of development, health inequalities persist in the same fashion (Deaton 2013; Marmot 2015). Given their development stage inequalities are associated with high levels of poverty and extreme poverty and other historical and cultural prejudices that create other dimensions of the inequalities such as the ones related to ethnicity or gender.

Among countries poverty and inequality levels, while correlated, are not similar. Among the lower-middle-income countries, higher levels of inequalities are observed in Latin American countries while higher levels of poverty are observed in other continents in particular, in Africa. It gives a complex picture of the lower-middle-income countries poverty and inequality distribution. For instance, in the effort to understand the reasons why LA countries have great levels of inequalities three axes were explored: its position within the global economic system, the internal colonialism that maintains racial categories and the underdevelopment of state structures (Hoffman and Centeno 2003).

In the current international context of economic globalization, discussions have highlighted inequalities within the same country but also inequalities between countries. Inequalities between countries are related to the differences in economic and social development achieved by different countries, which are generated by the position that these countries have occupied during different phases of history within the global productive system. The latter reflect historical aspects, and the international economic and political environment in relation to each country's share of global resources and development opportunities.

More recently, the concept of global inequality has arisen, which involves the combined effects of these two types of inequalities (Milanovic 2016). Global inequality is the result of inequalities both between and within countries, and it is therefore defined by the interaction of the determinants of each. The availability of international data has made it possible to conduct empirical studies regarding the issue of global inequality. For example, when the GINI Index, which is one of the most frequently used methods to measure social inequality within a country, is

calculated globally it results in even higher levels than those found in nations with the highest levels of social inequality. In recent years, the GINI indices of countries with the highest levels of inequality have been around 0.60 (1 = maximum inequality and 0 = total equality), while the global GINI Index is close to 0.70. The global GINI Index captures the extremes of the poorest strata of the poorest countries (low-income countries) and the richest strata of the richest countries (high-income countries), which translates into a higher level of inequality than when measured in each country separately.

Health inequalities

Poverty associated with an unfair wealth distribution in LMICs effects on health are staggering. It generates an estimated 800 million people chronically hungry, makes one in six children underweight, and more than one-third of deaths among children under 5 years to be attributable to malnutrition (Stiglitz 2012; FAO 2015; Johnston 2015). Insufficient access to safe and nutritious food exists despite the fact that global food production is sufficient to cover 120% of global dietary needs. Within each of these lower-middle-income countries social inequalities are observed among regions, inside regions, inside cities etc, or when societal or individual characteristics are considered (social class, ethnical groups, gender, etc.).

Looking overall the level of inequality (as measured by the GINI Index) is strongly correlated with different health indicators being life expectancy at birth, infant mortality, different infectious diseases incidence, non-communicable chronic diseases (NCD) report, or violence. For instance, the global average of the life expectancy at birth in 1990 was 64 years, while in 2013 that number had increased by seven years to 71 years. However, as averages these values conceal a series of inequalities. For example, at country level, in 2013, the average life expectancy at birth ranged from a minimum of 46 years (38 in 1990) in Sierra Leone (a low-income country), to a maximum of 84 (79 in 1990) in Japan (a high-income country). By 2013, life expectancy had increased in both countries and although the gap has narrowed slightly (from 41 to 38 years) they are still at unacceptable levels (WHO 2015).

Children are especially sensitive to social and environmental adversities. Despite advances in recent decades, it is estimated that 6.3 million children under the age of five died in 2013, mostly due to preventable causes in poor or developing countries. Children in low-income countries from sub-Saharan Africa are 15 times more likely to die before their fifth birthday than children in high-income countries. In 2015, the highest mortality rate was observed in Afghanistan (115 deaths per 1,000 live births) and the lowest was in Monaco (1.8 deaths per 1,000 live births) (Requejo et al. 2015). From 1990, when the Millennium Development Goals were established, to 2015 the global infant mortality rate fell from 62 to 32 deaths per 1,000 live births. Despite this substantial reduction (around 50%), the established target was not reached, which was to reduce the 1990 rate by two-thirds.

Today, infectious diseases continue to be the leading cause of death for children, and they are also a major cause of death in adults. Globally, three of the top ten causes of death are infectious diseases. These also account for 16% of deaths each year. Most of these deaths occur in poor and developing countries, and they are attributable to preventable or treatable diseases such as diarrhoea, respiratory infections, HIV/AIDS, tuberculosis, and malaria. Although there have been significant advances in interventions to prevent and treat most of these diseases, such interventions are not always available for the populations that need them. Taking the example of tuberculosis, which is a disease highly linked to the conditions in which afflicted populations live and whose occurrence changes rapidly when these conditions change, in 2013 it was estimated that nine million people became sick with tuberculosis worldwide, with most of these cases (56%) occurring in Southeast Asia and the Western Pacific. However, Africa had the highest incidence of tuberculosis, with 280 cases per 100,000 inhabitants. Of these cases, around 500,000 were caused by multidrug resistant tuberculosis (MDR-TB) bacilli, which, in addition to causing more severe diseases, often increase treatment costs, making them prohibitive for the majority of patients living in poverty. In the same year, the estimated total number of deaths from tuberculosis was 1.5 million. Of these deaths, more than 95% occurred in developing countries, although the death rate fell by 45% between 1990 and 2013 (WHO 2014). NCDs as a whole are responsible for a significant proportion of the world’s burden of diseases, accounting for almost two-thirds of global deaths (36 of the 57 million

deaths in 2008). The main health problems in this group are cardiovascular diseases, cancers, chronic respiratory diseases (such as chronic obstructive pulmonary disease (COPD) and asthma) and diabetes. Although other diseases, such as mental and neurological diseases (including various forms of dementia), contribute to the high burden of morbidity (lower mortality), they have not been prioritized in global plans. NCDs are increasing rapidly in developing countries, where they impose large-scale human, social and economic costs, many of which could be avoided with well-known, cost-effective, and feasible interventions. Although they were initially associated with wealth, evidence shows that about 80% of NCD deaths occur in lower-middle-income countries. Even in sub-Saharan nations, where communicable diseases, maternal and perinatal issues, and nutritional deficiencies are still more important when taken together, they are in decline, whereas cases of NCDs are growing rapidly. This picture has resulted in projections that by 2030 NCDs will be the most frequent cause of death on the African continent (Rasella et al. 2013; WHO 2013; Worku and Woldesenbet 2015).

It is estimated that more than five million (9%) of deaths occurring globally are related to various forms of violence. Approximately a quarter of these deaths result from suicide and homicide, and traffic accidents are responsible for another quarter. The various types of violence vary in different regions of the world, but, in general, their rates are always higher in poor and developing countries.

Within countries this difference is observed being gradients of health status, measured by different outcomes, or the access and utilization of health services are observed for among regions, among social or ethnical groups.

Development and inequalities in health: the role of the Agenda 2030

The Agenda 2030 recovers a fundamental debate on health justice. The Goal 3 ‘Ensure healthy lives and promote well-being for all at all ages’ implies a health standard which can be globally recognized. The target 3.8 ‘Achieve universal health coverage, including financial risk protection, access to quality essential health care services and access to safe, effective,

quality and affordable essential medicines and vaccines for all' is not explicit in relation to the role of the public sector as the main provider of health goods and services. However, it states that healthcare is local and global social concern, indicating that healthcare is related to social justice. The concept of social justice is explored in Chapter 2.3 ('Poverty, justice and health') in this Textbook (Labonté et al 2015). There is an important convergence for significant part of the moral philosophers in relation to healthcare as an essential component of the well-being and the societies have the moral obligation to make them accessible and affordable for all individuals (Ruger 2004). That leads the debate to another dimension: the need of a global health justice framework, which could direct global institutions and norms towards a globally shared principle of global heath obligations and rights (Ruger 2016).

Health and development are deeply interrelated issues: without a healthy population, a society will hardly achieve development, as will an incomprehensible paradox if a society does not include the health of its population among the main objectives of its development.

Both issues have been on the United Nations' global agenda since its inception in 1945. In the 1960s, anticolonialist liberation struggles, which resulted in the independence of several African countries and other regions, gave renewed impetus to both issues. However, successive economic crises and strategies formulated in the 1970s and 1980s did not live up to the 'right to development' expectations of most underdeveloped countries. In health, the strategy of primary healthcare was drawn up since 1975, with its culmination in the Alma Ata Conference and Declaration in 1978. The relative failure of development policies led the United Nations to make efforts in practically all its agencies to review their policies and practices in the 1990s by holding international conferences to 'prepare the world for the 21st Century' (UNDESA 2018).

In 2000, at its headquarters in New York, the United Nations held the Millennium Summit (General Assembly 2000), which issued the Millennium Declaration (General Assembly 2000) with a set of eight Millennium Development Goals (MDGs) and 21 development goals to be achieved by the year 2015, measured by 60 indicators. Despite some recognized progress to many authors and the United Nations itself the major development goals were not achieved. Despite this, taking on the 'unfinished agenda of the MDGs', the United Nations and its Member

States insisted on the process, replacing in 2015 the Millennium Development Agenda with the 2030 Sustainable Development Agenda (General Assembly 2015), with its 17 goals and 169 targets to be met by 2030, compliance with which will be measured by 232 indicators.

The Rio + 20 Conference, held in Rio de Janeiro in 2012 (UN General Assembly 2012), builds the political foundations of Agenda 2030 and its Sustainable Development Goals (SDG), whose central mantra 'leave no one behind' clearly indicates the radical political rhetoric of the UN and its Member States by the reduction of inequalities between and within countries. The concept of managed sustainable development indicates that it will be realized through the articulation of its three dimensions—economic, social, and environmental—to be realized in the global, national, and local plans. There are reasonable degrees of freedom for each country to seek on the 'menu' of Agenda 2030 and its SDG to set up its own Development Agenda.

It can be said that Agenda 2030 and its SDG are potentially the most relevant global public policy underway to overcome inequalities in society, including in the field of health.

Funding for global development is suggested in the Addis Ababa Agenda for Action (AAAA) (UN General Assembly 2015a, b). The final text of the outcome document, adopted at the Third International Conference on Financing for Development (Addis Ababa, Ethiopia, 13–16 July 2015) and endorsed by the General Assembly in its resolution 69/313 of 27 July 2015, was one of the changes in relation to the Millennium Agenda. While it was basing its funding strategy on building a global development alliance in which official development assistance (ODA) gained importance, the AAAA stipulates that development must be pursued by each country for the openness, albeit asymmetrical, of its markets to international capital investments, which would inevitably lead to development. Numerous experts (including ourselves) doubt that simple trade liberalization can induce sustainable and equitable development, as advocated by Agenda 2030; in fact, the induction and participation of the democratic state is essential in the formulation and implementation of equitable and inclusive development policies.

Overcoming health inequalities is clearly stated on the SDG 3: 'Ensuring health and promoting well-being for all ages', but this concept does not

translate into a set of proposed goals and means of implementation capable of achieving the goal.

This gap between the intention of the goal in health and the means to achieve it is perhaps the main weakness of the Agenda in this area. It is a considerable task for United Nations sectorial agencies in the area—made up of the World Health Organization (WHO), its regionals, and the countries' Ministries of Health—to be able to find, with the support of civil society and users, the ways to adequately translate the politically powerful and far-reaching Objective into achievable goals and indicators that can measure the effective achievement of overcoming health inequalities, particularly in developing countries.

Among the proposed strategies are Health in All Policies (WHO, 2013) with the understanding that given the multidimensional nature of human health, governments need to assess the positive and negative effects of economic, social, and environmental policies on health, including in reducing inequalities. This strategy is supported by the highest policy body for conducting SDG implementation at the global level, the High-Level Political Forum (HLPF), with its 'From silos to integrated policy making' orientation, which explicitly recommends the adoption of integrated multisectoral and harmonious policies for achieving sustainable development, in accordance with the precepts of equity and inclusion.

The political rhetoric of Agenda 2030 and its SDG, including SDG 3, for health, establishes high-level global agreements for reducing health inequalities in developing countries. However, its concrete implementation will depend on the effective political will of the whole society and government—executives, legislators, judiciaries, and civil society—to translate into national development plans designed as a strategy for sustainable development in almost all countries.

Urban transition and health inequality

Demographic and epidemiological transitions are shaping and being shaped by urbanization. The demographic aspects combined with the urban built environment have influenced the conditions of living and, therefore, becoming ill or dying.

Fertility and mortality trends influence the age composition of populations, which, consequently, influences morbimortality patterns. The links between morbimortality patterns and population dynamics are commonly studied within the epidemiological transition theory. In emerging countries for example, three components of the population dynamics (fertility, mobility, and mortality) seem to be strongly associated with urbanization. Urbanization presents controversial impacts on health. If on the one hand the urban citizens are more likely to be reached by health, hygiene policies, and food availability, on the other they are also exposed to risks related to industrial sources, overfeeding, violence, and psychosocial factors. This means that a contradictory scenario tends to take place in the cities, especially, in developing countries (Eckert and Kohler 2014).

Since the mid of 20th Century, the emerging urban population has faced dramatic changes in morbimortality patterns. When compared to rural areas, emerging cities present lower levels of morbimortality due to infectious diseases and undernutrition, while presenting higher levels of morbimortality due to chronic diseases (Eckert and Kohler 2014). In the cities the levels of fertility have declined largely in the last 50 years as well. This suggests that the urban population tend to present better conditions in terms of sanitation and medical care and more exposed to widespread ideas on birth control (Bongaarts 2017).

However, mortality rates due to infectious diseases (including neglected diseases) and undernutrition vary within the city, suggesting that the gains of urbanization are not equally distributed among all settlers. When examining disaggregated data, intraurban variations expose the health inequality patterns across the urban territories (Hotez 2017). Socioeconomic differences and uneven morbimortality patterns have been a usual scenario in emerging cities.

Migrations and the limits of human movements

Since time immemorial, sectors of populations or even whole populations have moved to new destinations for various reasons. In 2013, it was estimated that 232 million people—3.2% of the world's population—lived outside their country of birth, and another 700 million were internal migrants in their own country of birth (UNDESA 2013). The patterns and

motives for these migratory movements have changed greatly over time; however, it is clear that the majority of migrants who cross national borders do so in search of better economic and social opportunities. In recent decades, exacerbated disparities between nations, global economic expansion, geopolitical transformations, wars, ecological disasters, and many other occurrences have had, and will continue to have, a profound impact on people's decisions to move to other nations. The recent phenomenon of the massive migration from some Arab countries to Europe is an example of the explosive and uncontrolled possibilities that the migratory issue can generate (Social Europe 2018).

The migratory issue introduces an important point into the debate on inequalities. Estimates show that social inequalities between countries account for a larger share of global inequalities than inequalities within countries. While inequalities within nations are much more related to class issues and other processes of social stratification, inequality between nations raises the issue of place of birth, or what has been termed the 'citizenship prize', which is related to history and the overall process of development of nations. Taking the question of life expectancy, a child born in Sierra Leone in 1990 only had an average life expectancy of 38 years, which was less than a child born in Japan in the same year (46 years compared with 84 years). Therefore, the issue of where one is born takes on great importance, and the migratory movement is defined by this attempt to change what was to some extent established by one's place and moment of birth. However, in a globalized world, in which capital, commodities, and human beings circulate, there are serious limitations on the movement of people, especially when they wish to move between nations.

Defining contexts on health inequalities

The essence of the health inequality is the uneven variation of health indicators among the individuals due to their social characteristics. That variability can be accessed through the stratification of the individuals according to available social characteristics data. Evans and Brown (2003) described the most used social characteristics in health inequality studies. It is summarized by the acronym PROGRESS, relating to first letter of the following set of variables: Place of residence (rural, urban, etc.); Race or

ethnicity; Occupation; Gender; Religion; Education, Socioeconomic status; and Social capital or resources. That comprehensive list of equity stratifiers for studying health risks and morbimortality does not consider some characteristics that are present in the literature. Age for example can be an equity stratifier if that condition is associated with unfair access to health services, as it occurs in many countries where adolescents have no access to contraceptive methods (WHO 2013). The relevance of each stratifier varies on time and space. In the recent years, large-scale involuntary migration emerged as one of the most relevant political items in the agenda of many countries, producing important shifts on national politics and international aid priorities in Europe. As a consequence, the health researchers elected health inequalities associated with race and ethnicity as a relevant investigating topic. Some findings revealed the impact of anti-immigration politics on health systems. In Barcelona in 2012, changes in the legal framework constrained immigrants to access health services (Castano 2016). In the Latin America and the Caribbean countries, race and ethnicity are relevant for observing the unfair distribution of health goods and services among national groups.

However, the migration is not frequently considered neither a prevalent nor a relevant topic on population health studies. Data availability and scientific tradition also interfere in the preference for some stratifiers. In Brazil, income is a very commonly used stratifier, while in South Africa, multivariable indicators, such as household socioeconomic status, are most popular. A common criticism related to the use of equity stratifies is the narrow representation of the social vulnerability captured by a single social dimension associated with one health indicator (WHO, 2013). In fact, vulnerable contexts (such as poverty in poor countries) encompass a large number of stratifiers which are entangled producing a complex picture of this vulnerability.

The growth in health inequalities: possible solutions

The construction of a more equitable world has been the aspiration of different political movements which understand that reducing inequalities in the various spheres of human life is essential and guarantees the existence and sustainability of human society. Health inequalities expose one of the

facets of inequalities that are prevalent among human beings, the cruel and damaging effects on one's own existence, which is reflected in the immense differences in life expectancy or the burden of disease and suffering.

The evidence of the importance of social determinants in explaining health inequalities is compelling. However, although there are clear academic and political arguments that favour the implementation of actions to redress the determinants of health inequalities, policies to mitigate these inequalities have been scarcely implemented as part of the public policies of national governments, and still less to alleviate inequalities between nations. There are several reasons for this lack of political motivation; however, some aspects have been recurrent in the literature regarding health inequalities.

One of the first aspects to consider is the consolidation of a health system based on biomedical knowledge and the resulting technologies, together with strong industrial and service sectors. These forces tend to generate and consolidate health systems that are only slightly affected in conceptual and structural terms, or favour actions directed at the social determinants of health.

It is worth noting that the existence of inequalities, and their magnitude, does not immediately result in moral imperatives or generate political action within a society. In some societies, relatively small levels of health inequalities have generated strong policy actions to reduce them (e.g. some Scandinavian countries), while others, with broad levels of health inequality, are not motivated to alleviate them as happen in a major part of the LMICs.

In poor and developing countries, where health inequalities are of the highest magnitude, there are few examples of the latter being among the priorities of public policy. For example, following the establishment by the WHO of its Commission on Social Determinants of Health, Brazil, which is a country with immense social and health inequalities, created its own national commission. However, after 2 years of work this commission produced a report which, in the main, was not assimilated into government actions (CNDSS 2008). Nevertheless, over the past two decades the implementation in many developing countries of redistributive policies such as income-transfer and micro-credits (von Gliszczynzki 2015), which are non-health policies, have had positive effects on health inequalities (Rasella et al. 2013). With regard to inequalities between countries, the proposals

and actions have been even more timid. For example, the final report of the WHO Commission on Social Determinants of Health (CSDH 2008; Landmann-Szwarcwald and Macinko 2016) places great emphasis on inequalities within a particular society and less on inequalities between nations. It has a chapter dedicated to the issue of health inequalities in the global sense, which focuses on the need to strengthen so-called global governance and explains the need for coordination among various intergovernmental agencies. Some of these ideas were subsequently deployed in policies, such as the MDGs, which focused on the eradication of extreme poverty from 2000 to 2015 and their successor, the SDGs, which include the additional aspiration of sustainable development in its three forms (economic, social, and environmental) during the period 2016–2030.

More recently, another group (*The Lancet*, the University of Oslo Commission on Global Governance for Health) (Ottersen et al. 2014) has made advances in understanding and proposing actions about global inequalities. The latest document produced by this group entitled 'The Political Origins of Health Inequity: prospects for change' is intended to 'convey a strong message to the international community and to all actors who influence global governance processes: we must no longer simply consider health to be a biomedical, technical issue; we recognize the need for multisectoral and global actions and justice to address health inequalities' (Ottersen et al. 2014, p. 631).

In conclusion, although interest in the issue of health inequalities has increased from the academic point of view, this interest has only had a limited impact on public policies aimed at improving the health of populations. Social inequalities in health are a global problem that, to a greater or lesser extent, affects all human societies. They are mainly due to the inequalities that exist between the different social groups in each society. Although the inequalities that exist between different societies and nations are relevant, and are often of a greater magnitude, they are not always considered to be unjust, and as such they are subject to political actions. The most plausible theory that has been put forward to solve the latter type of inequalities has been to improve the mechanisms of global governance, insofar as this includes an understanding of how nations were historically founded and the effect of the position of each country in the productive global system (Robinson and Acemoglu 2012).

How to reduce health inequalities in developing countries?

Combating health inequality demands an articulation of different actions that are associated with its determinants. A comprehensive approach should consider: (1) To be a distinguished goal of the national health policy; (2) To intervene on social determinants of health inequality; and (3) To improve living conditions and to overcome the exclusions mechanisms related to barriers for reaching the health systems.

It is difficult to access the national commitment on converting a public goal into effective policies. In Latin America, the concept of 'social institutionalization' has been used to access such degree of governmental commitment. According to Repetto (2004), social institutionalization refers to a set of formal and informal norms, including routine and organizational behaviours, necessary to process and to prioritize the social problems, delimiting the content and the political and administrative dynamics of social policies.

Cruces and Machinea (2010) have highlighted some institutional attributes that can be amplified to state level scale while defining a strategy for fighting health inequality: clear norms and goals, and sustainable policy. The issue of health inequality should be intrinsically part of the health policy with clear and stable norms and goals based on explicit political agreements and legal framework, with its sustainability been assured by adequate funding policy.

Martínez (2017) has performed an extensive review of the Latin American literature on social institutionalization. The following list highlights selected components based on aforementioned authors' reviews that tend to be relevant on the subject of reducing health inequality:

Consistent and sustainable long-term strategy. That indicates a resilient policy with the capacity to go beyond electoral cycles and ready to respond to economic and political shocks.
Social justice approach, as just explained.
Coordination *Fora*. Health inequality policy requires a large number of actions from different areas and levels. The coordination of different actors from different *loci* and interests requires specific spaces of horizontal and vertical coordination with mandate and capacity for easing divergences and identifying the best cost-effective solutions.
Development of technical capacities. A great limitation for implementing any action is the lack of qualified professional for implementing the adequate procedures. In developing countries, that is aggravated by the high turnover of the limited trained personnel as a consequence of precarious labour contracts and low incomes.
Social participation. That comment is strongly associated with the long-term sustainability of policy and programmes and will be further explored in the next section.

Interventions on social determinants of health inequalities are strongly associated with the reduction of morbimortality in vulnerable populations. Currently, the most effective approach to reduce poverty, extreme poverty, and social inequality is the use of articulated interventions to confront different factors associated with population vulnerabilities. Investment on education, labour policies, social protection, gender policies, and housing, compose the set of public policies that are often associated with the promotion of health equalitarianism. Ideally, a combined approach would seek to:

Promoting social development. Restoring the broader dimension of the concept of development in order to integrate an excluded population into the national and local economic and social dynamics.
Promoting equity. Using public policies to reduce unjustifiable differences and fighting discrimination. Reducing the poverty gaps faced by minority groups such as: black, indigenous, and traditional populations.
Generating opportunities. Human capital development considering gender, place of residence (urban or rural), and cultural context.
Improving quality in the delivery of public goods and services. The main deficit faced by the vulnerable populations is lack of access to quality public services.
Developing a sustainable policy. The endogenous and exogenous factors that can affect the programmes and policies sustainability should be considered while developing the model.

Box 2.5.1 presents the recent change in the Mauritian strategy to fight poverty and extreme poverty named as The Marshal Plan. An observation of its components can be useful for countries with some capacities but with huge social inequality.

Box 2.5.1 Marshall plan against poverty in Mauritius

Mauritius is implementing the Marshall Plan, aiming to fight poverty and inequality using an articulated set of 39 interventions from the areas: social protection, employment, social housing, education, health, environment, and equity in service delivery. The success of the plan lays on: (1) mobilizing all sectors, including private sector to reduce poverty and inequality; (2) produce institutional arrangements of public sector in order to avoid redundancy, overlapping responsibilities and waste of resources; (3) empowering the public institutions responsible for promoting community-based approach; (4) setting official poverty line for harmonizing the concept across public institutions; (5) improving technological capacity for accessing the needs and service performance; (6) developing creative mechanisms for funding pro-poor actions.

The first intervention is to fill the poverty gap in the whole country using conditional cash transfers. Many specific interventions on the poor areas are expected to produce positive impacts on the reduction of the health inequality, such as: dismantling of asbestos housing in 5 years; implementing community-based childhood care and education services; implementing community schools to promote emotional, physical, and creative learning.

One group of interventions was designed to reduce the barriers to access basic health services. The implementation of mobile clinics for youth-friendly and stigma-free healthcare services for providing sexual and reproductive healthcare services for youth, sex workers, people living with HIV/AIDS, people who inject drugs, and men who have sex with men.

Other community-based environmental interventions were designed to improve the sustainability in the poor areas. They comprise: increase waste recycling; producing income generating green jobs in textiles and manufacturing; developing alternative livelihoods from coastal and marine zones in management of communal forests and sustainable collection of native plant species; and to enhance ecotourism.

A third layer of policy interventions refer to improve living conditions and to overcome the exclusions mechanisms related to barriers for reaching the health systems. Living conditions encompasses a wide list of factors such as health behaviours and the hazards present in the working place. In relation to health behaviours is well known that tobacco consumption and poor diet are associated with socioeconomic status both in developed and developing countries. Thus, price interventions can reduce health inequalities, such as increasing taxation on unhealthy habits (alcohol and tobacco consumption) or providing subsidy to stimulate the healthy ones (Hill et al. 2014; McGill et al. 2015). Interventions to control diseases associated with poverty are also part of the strategy to reduce health inequality. More challenging is to promote the reduction of the barriers to access the health services. Kidd (2017) has used the concept of *social exclusion* to identify the main barriers of access to social policy services, as 'the process through individuals or categories of the population are wholly or partially excluded from full participation in the society in which they live'. He identifies three dimensions that restrict or block the access of vulnerable populations to diverse social programmes. He three dimensions require specific strategies for dealing with associated problems. The Kidd's social exclusion dimensions are described below, with focus adjusted on main problems and practical policy responses present in health sector:

Exclusionary forces. It is related to the view from those sectors that hold major share of power in the society over marginalized groups. Civil servants and institutions become embedded by discriminatory practices, institutional blindness, and no recognition of claims demanded by some groups. A large number of populations groups can be affected by discriminatory practices, such as: indigenous populations in Latin America, religious minorities in Asia, women in Arabic countries, Albinos in Africa, and disabled population in many continents. Recent interventions in Mauritius (Box 2.5.1) and Bangladesh (Box 2.5.2) have aimed to remove the barriers to health services and social protection schemes.

Structural disadvantages. They comprehend infrastructure deficits (such as roads, transportation, health facilities), lack of telecommunications systems, exposure to natural disasters (such as water crisis), and low levels of economic activity, interfering in all provision of services market. They are very associated with geographical factors and low economic dynamism of the areas located is the countryside of developing countries. Botswana (Box 2.5.3) have promoted an extensive shift on health programmes in order to improve the infrastructure of health services in poor rural areas. Brazil (Box 2.5.4) also present a relevant experience of how the interactive effects of primary healthcare and social transfers programmes can reduce morbimortality related to poverty-related diseases.

Limitations in capabilities. Some individual states or attributes may reduce the capacity to engage with public authorities and civil servants. The list of conditions is extensive, such as: disabilities, mental disorders, low education (literacy and numeracy), poor linguistic fluency, being exposed to domestic violence and abuse, low self-confidence, lack of available time, care responsibilities for children, elderlies, and ill persons.

Box 2.5.2 Reducing poverty-related diseases in Bangladesh

Bangladesh is one of the most populated, dense, and disaster-prone country in the world. With a territory of almost the size of England and Wales together, it accounted for 163 million people in 2016. In the last 20 years, it has achieved remarkable results on improving child and women health, despite of its modest public spending in health (2.6% of GDP in 2015), with meagre domestic general government health expenditure (0.39% % of GDP) in the same year according to the World Bank. The impressive health achievements at low cost turned Bangladesh in a role model for developing countries in the region (WHO 2015).

A mix of actors (public, private, and NGO) have contributed for the achievements on rapidly improvement of health indicators, such as infant mortality, under-5 mortality, and maternal mortality rates, morbidity rates from some infectious diseases including malaria, tuberculosis, diarrhoea, visceral leishmaniosis, HIV/AIDS, nutritional deficiencies, immunization coverage, and access to medicine (WHO 2015). Between 1990 to 2015, the under-5 mortality rate and maternal mortality ratio fell, respectively, to 73.8% and 69.1% (Ahmed 2016). The fall in mortality has produced significant impact in both life expectancy at birth and in fertility rate. Between 1990 and 2016, the total life expectancy at birth jumped from 58.4 to 72.49. When stratified by gender, that gains are greater for women. For men, the variation for this indicator in the period was from 58.05 to 70.89, while for women it moved from 58.78 to 74.29. Between 1990 and 2016, the total fertility rate declined from 4.49 to 2.1 (World Bank 2018). The demographic indicators suggest significant improvement of health conditions for women. That is a remarkable achievement for a patriarchal society with a tradition of gender disparities in all areas.

The results are associated with actions from different sectors, including health, education, social protection, infrastructure, and economic development. Some health programmes achieved international recognition such as: expanded immunization programme, oral rehydration, prevention, and treatment of targeted infectious diseases and undernourishment. An interdependent set of determinants are associated with these heath gains, such as the increase in female schooling, which in turn was strongly stimulated by the Female Stipend Programme designed to increase female secondary education and to delay marriage and childbearing (Hahn 2018).

Box 2.5.3 Fighting poverty as part of development strategy in Rwanda

After violent conflicts in Rwanda in the mid-90s, that included a genocide in 1994, the country experienced a rapid and sustained growth, sharp poverty reduction, and reduced inequality. According to Verpoorten (2014), among the most relevant drivers are: massive aid; increased public investment on health, education, and agriculture; the fertility transition; and the rise in international prices of the commodities.

The World Bank Open Data allows for comparison between the immediate post-conflict period with the current context. The net official development assistance received by the country increased from USD$321 million (2000) to USD$1.148 billion (2016). The secondary school enrolment (% gross) increased from 11% (2000) to 37% (2016). The health indicators presented substantive improvement, such as: the total life expectancy grew from 48 years at birth (2000) to 67 years (2016), and the total fertility rate declined from 5.6 births per woman to 3.9, respectively, in the same years of reference. Its economic prospects are marked by the real GDP growth averaged at about 8% per year (between 2001 and 2015).

The development policy of Rwanda is shaped by the Vision 2020 (long-term) and the second Economic Development and Poverty Reduction Strategy—EDPRS 2 (medium-term). They stress the combination of economic with social goals, such as: economic transformation with poverty reduction, e.g. moving the country from agriculture-based economy to knowledge-based and service-oriented-economy while reducing the percentage of population living on poverty from 30% by less than 9% by 2020 (World Bank 2017).

Rwanda also promoted a health sector reform that produced a relevant impact on maternal and infant health. According to Bucagu (2012), between 2006 and 2010, the improvements on the heath sector was particularly high in rural areas as a consequence of scaling up of facility-based childbirth policy based on: the heath workforce skills, performance-based financing, community-based health insurance, better governance.

The data compiled by the World Bank Open Data accounts that under-5 mortality rates per 1,000 live births fell from 195 in 2000 to 39 in 2016. That is strongly correlated with the rise in the coverage of the proportion of births attended by skilled health staff, which raised from 31% (2000) to 91% (2016). The DHS 210 allowed for comparison between the top and bottom quintile of wealth, indicating small difference on health indicators between the two groups, such as: antenatal care (at least one visit), DPT3 and measles immunizations, full immunization coverage (1 year), early initiation of breastfeeding, vitamin A supplementation (WHO 2013). The difference in percentage points between the two groups (top/bottom) varied from –1.6 (early initiation of breastfeeding) to 8.6 (full immunization coverage). At that time, the biggest difference was related to births attended by skilled health staff. The access of the bottom quintile was 61.2% while top quintile was covered by 85.9%. The subsequent progress on the indictor had reduced that gap.

Box 2.5.4 The interactive effects of primary healthcare and social transfers on the reduction of health inequalities in Brazil

From 1981 to 2014, Brazil presented one of the most remarkable drops in poverty in the world. According to the World Bank Data (2018), the poverty head count ratio at US$ 1.90 a day (2011 PPP) fell from 21.4% to 2.8% of the population in the period. The indicator refers to the population classified as ‘extreme poor’. From 1980 to 2014, according to the Brazilian Census Bureau (IBGE), the infant mortality rate (per 1,000 live birth) fell from 69.12 to 14.4, suggesting that the gains on poverty reduction influenced the improvement of public health indicators, as it is largely described in the scientific literature in relation to different countries. What is surprising is the fall of the GINI Index that was long stabilized from 1981 to 2003 around 58, reaching 51.3 in 2015 (World Bank 2018). Three determinants seemed to be associated with the reduction of poverty and inequality: the rise of the formal employment and the minimum wage, and the fast increase of the coverage of the social transfer programmes, which Bolsa Familia Programme is the major one in Brazil. The former was particularly relevant for protecting the extreme poor population against socioeconomic adversities, accounting for 66% in the reduction on the severity of poverty (Tesouro Nacional 2016).

The Brazilian primary healthcare programme (Family Health Strategy, FHS) is the biggest of its kind in the world. In 2018, it covered 206 million people (98.5% of the Brazilian population). More than 263,000 community health agents, organized in more than 42,000 teams, deliver a comprehensive and preventive healthcare services to the local populations. There is strong evidence of the contribution of the FHS on the reduction of infant mortality, in particular post-neonatal mortality due to diarrhoea and respiratory infections, also improving oral health, and increasing the detection of neglected disease and the reporting of vital data (Macinko and Harris 2015). Despite being a universal programme, its presence is more relevant to poor populations that use only the public health system, which contributes to the reduction of health inequalities. The FHS has contributed to the reduction of the disparities between Black/Pardo and White populations in relation to deaths due to ambulatory-care-sensitive conditions (Hone et al. 2017).

The effect of the poverty alleviation (including better nutrition) component of the Bolsa Familia with the incentive for accessing FHS is associated with the reduction of under-5 years of age mortality (Rasella et al. 2013), and the incidence of tuberculosis (Nery et al. 2017) and leprosy (De Andrade et al. 2018), among the poorer municipalities.

The interactive effects of social transfer and high coverage primary healthcare programmes are not only effective, but also very efficient. In 2017, the investment on Bolsa Family Programme

represented only 0.43% of the Brazilian GDP, while FHC responded for just 0.31 of the GDP (Senado Federal do Brasil 2018).

Social participation

Social participation is usually indicated as a condition for the sustainability of health inequality interventions in terms of funding, content, and governance. When active, it can prevent political interference on the health systems, specially under the shift of governments. It is considered a fundamental component of the institutionalization process and referred in many targets of the Agenda 2030. However, social participation refers to a wide set of engagements of representatives on policy fora, including inequalities of access to decision-making processes.

Arnstein (1969) described the participatory process as a ladder with eight steps, which social participation would vary from information to citizen control, e.g. different degrees of access to power from convening only to inform about decision taken elsewhere to effective participation.

Gaventa (2006) suggests a more complex model (cube shape), which participation can vary in three different levels (local, national, and global). The spaces for participation can be closed, invited, or claimed/created. And forms of power *per se* can be:

Visible, if the decision-making process is observable;
Hidden, if the setting of the political agenda is controlled by powerful individuals and institutions;
Invisible, if the controllers operate through psychological or ideological mechanism, preventing the appreciation of inconvenient topics.

Conclusions

In the recent decades, poverty has presented a sharp decline in all regions. However, in Africa, Asia, and in the Americas, poverty is still a vulnerability experienced by large parts of the population. That risk is exacerbated by economic crises that exterminate jobs, and shrink the fiscal space, thus compromising the countries' level of social protection and

safety nets. The face of poverty and the extreme poverty is changing, becoming more urbanized and affecting the older population, while remaining highly concentrated in rural areas and among children. If poverty is moving down, socioeconomic inequality is growing in size and complexity. Global and national wealth concentrations challenge the capacity of the states to produce equity, integration, and the feeling of living in a fair society.

Both poverty and inequality are no longer isolated national issues. The degree of economic and cultural integration at the global level shows how the prosperity of some social groups across the planet may be connected, through a complex web of economic unfair advantages, to the unfavourable condition of far larger population groups. The migration crisis faced specially in Africa and Asia, and secondarily in Europe illustrates that natural disasters, political conflicts, economic crises, religious or ethnical rivalries can drive masses of destitute people towards safer areas, expanding the effects of a context, which combines recent crisis with historical poverty to other regions.

Poverty and inequality interfere on the health dimensions: determinants of health, access to promotive and preventive actions, and health intervention. As a consequence, an inequal health patterns of diseases, deaths, and disabilities flows across the different population groups. Health inequality is present across the planet with far more intensity on the poorer areas and dwellings.

Policies for fighting poverty and inequality require local, national, and global approaches. The Agenda 2030 is a laudable initiative for presenting a multisectoral approach for confronting simultaneously health problems and their social determinants. The commitments of the countries encompass fighting poverty, hunger, health problems, and inequalities in articulation with environmental and economic interventions. However, the lack of a clear funding strategy limits its feasibility.

National and local interventions have decisively contributed to reducing health inequalities. Leveraging social participation has helped to promoting public policies for reducing health inequalities. Different health and other social policy initiatives from countries such as Bangladesh, Rwanda, Brazil, and Mauritius show alternatives ways for improving the health status of the population while reducing health inequalities.

Genomics and public health

Veron Ramsuran and Tulio de Oliveira

Introduction

In the last two decades there have been several significant advances in the field of genomics. Some of these advancements include, the completion of the Human Genome Project in 2003, use of genomic tools to diagnose patients at point-of-care facilities, and the use of gene editing technology to cure several diseases. The discipline of ‘public health genomics’ emerged as a need to provide ‘responsible and effective translation of genome-based knowledge and technologies for the benefit of the population’ (Bellagio 2005, in Bellagio 2019). It is becoming increasingly accepted that the one size fits all approach is going to be outdated soon. Targeted personalized medicines, therapies, and interventions approach will be the preferred form of treatment in the not too distant future (Molster et al. 2018).

Genomics has served as the platform for ‘precision medicine’, which utilizes the advances made by genomic technologies to provide information that is person centric. Determining the interactions of an individual’s genes, environment, and lifestyle to deliver a targeted intervention specific to that person (Khoury et al. 2017). The rapid advancement of genomic technologies has led to significant volumes of individual and population level data. Combining data generated, at the individual level on genes, environment, behaviour, and other social and economic determinants of health, provide a useful new approach of utilizing big data to guide the right intervention to the right people at the right time, has been termed ‘precision public health’ (Khoury et al. 2017).

The fields of public health genomics, precision medicine, and precision public health have proven important aspects in improving population health. However, despite the advancements made, there are still

improvements that need to be implemented to significantly improve health, especially within the developing countries. In this chapter we discuss the advancements made within the field and highlight challengers or future directions.

Genetic variation has been shown to associate with a number of clinical outcomes. These variations could be single nucleotide polymorphisms (SNPs), combinations of SNPs within a gene or in multiple genes and chromosomal aberrations (Molster et al. 2018). Genetic testing can be used as a diagnostic or a predictive tool to screen individuals who present with or are at risk for a particular disease or to determine a suitable course of treatment through pharmacogenomic studies. As a predictive tool, it allows for newborn screening of metabolic diseases such as phenylketonuria, it can be used to determine if individuals are carriers of a recessive trait which can be passed on to offspring, it allows non-invasive testing of foetuses for genetic disorders or chromosomal abnormalities and it can also be used during *in-vitro* fertilization to test if an embryo has a particular genetic or chromosomal abnormality. Genetic testing methods vary depending on the question being asked. Simple tests such as SNP genotyping and target gene capture with sequencing are used for single-gene disorders or Mendelian diseases. Chromosomal disorders on the other hand are abnormalities of the chromosome structure or number and these are detected usually through karyotype analyses which reveals minimal information about the genetic code itself. Finally, there are the polygenic diseases that are caused by a collection of mutations that may occur across a number of different genes contributing to a given phenotype (Khoury et al. 2017). For example, there are several combinations of mutations that can lead to hypertension, coronary artery disease, and neuropsychiatric disorders. Testing for these disorders can sometimes be more complicated especially when the causative genes are unknown. When the causative genes are known, targeted sequencing of specific genes can be performed. However, when they are unknown it becomes more beneficial to perform whole exome (WES) or whole genome sequencing.

The era of genome-wide association studies has allowed us to identify variants across the genome that contribute to a disease phenotype. Many of the variants identified that reach genome-wide significance are found within the non-protein coding regions of the genome. One of the major benefits of performing whole genome sequencing (WGS) is that it covers variation in

the coding and non-coding regions of the genome. Another is that WGS data from an individual does not change over time and contains a plethora of invaluable information about the health outcomes one might experience in their lifetime (Molster et al. 2018).

Public health genomic tests currently in use

The rapid proliferation of genetic tests has made it possible to detect a range of health problems at the clinic level or direct-to-consumer for personal genetic tests. According to the Genetic Testing Registry (GTR) (https://www.ncbi.nlm.nih.gov/gtr/), a central location of submitted genetic test information hosted by the National Institute of Health, has 60,027, 11,971 conditions, 18,631 genes from 526 labs across the world (last accessed 16 August 2019) (NCBI 2019). The United States still dominates the number of labs contributing to the GTR, about 50% of the information submitted originates from a United States-based laboratory. The conditions reported range from several rare diseases to a variety of common diseases. The risk assessment, predictive, diagnostic, and prognostic are described for the tests. The information provided on the GTR is voluntary based submissions and is not verified for accuracy (NCBI 2019). The application of these tests ranges from diagnostic, predictive, and reproductive genetic testing, which could be used in response to a specific clinical problem or as a screening tool.

Diagnostic genomic testing

The diagnostic genomic testing is often used to confirm a clinical diagnosis. The genetic information obtained proves valuable to relatives and for monitoring of treatment. The finding of genetic makers observed within an individual that is linked to an inherited disease should encourage their family members to perform the diagnostic test (Molster et al. 2018).

Predictive genomic testing

Genetic variants linked to a person’s risk of developing heritable disorders are used as predictive tools or biomarkers. There are a few tests that have

received significant attention due to their usefulness for screening before signs or symptoms appear. These predictive tests include screening for cancers, newborn diseases, and pathogen detection.

Hereditary breast and ovarian cancer

More than 50 hereditary cancer syndromes have been reported and genetic predictive testing is available for most of these cancers (NCI 2019). Mutations within the *BRCA1* and *BRCA2* genes have been associated with Hereditary Breast and Ovarian Cancer (HBOC). These genes have tumour suppressor abilities and serve the function of repairing damaged DNA. Therefore, mutations within these genes inhibits the overall functioning. In breast cancer mutations account for 5% of all cases, while within ovarian cancer mutations account for 10–15% of cases (Armstrong et al. 2019). Women with *BRCA1* and *BRCA2* mutations have a significantly higher lifetime risk of developing breast cancer (about 50–85%) and ovarian cancer (about 15–40%) chance. There are several thousand mutations that have been identified within the *BRCA1* and *BRCA2* genes (BRCA 2019). Many of these mutations do not contribute towards cancers, while certain mutations have the ability to cause truncated proteins when translated. Understanding the genetics basis of mutations with regards to HBOC from diverse ethnic backgrounds around the world is the aim of collaborative efforts like the BRCA Exchange programme (BRCA 2019). Resources that provide clinical significance of genetic variants specific to the country and ethnicity an individual originates from has greater relevance to the patient than general information.

Apart from *BRCA1* and *BRCA2* genes, which show the strongest lifetime risk for developing breast cancer, other human genes have also been linked to breast cancer predisposition. The genes identified and the lifetime risk for breast cancer are TP53 (50–80%), PTEN (50–85%), CDH1 (39–52%), STK11/LKB1 (35–50%), PALB (20–30%), CHEK2 (15–25%), NF1 (15–25%), and p16 (15–25%) (NCI 2019). Risk genes for ovarian cancer include BRIP1, RAD51C, and RAD51D (NCI 2019). Genomic testing is currently being offered direct to consumers or through healthcare providers and genetic counsellors.

Newborn screening

Infants that are a few days old undergo predictive testing as a form of newborn screening (NBS). A growing list of NBS tests provide predictive evidence that an infant is at risk for certain metabolic, hormone, and genetic diseases (Therrell et al. 2015; Urv and Parisi 2017). The metabolic disorders NBS examines includes; phenylketonuria (PKU), methylmalonic acidaemia, maple syrup urine disease (MSUD), tyrosinemia, citrullinemia, and medium chain acyl CoA dehydrogenase (MCAD) deficiency. Congenital hypothyroidism and congenital adrenal hyperplasia are the hormone disorders tested. Some of the other disorders tested can include sickle cell disease, haemoglobin SC disease, beta thalassemia, galactosemia, biotinidase deficiency, cystic fibrosis, severe combined immunodeficiency (SCID), Pompe disease (glycogen storage disease type II), mucopolysaccharidosis type 1, X-linked adrenoleukodystrophy and spinal muscle atrophy (SMA) (Therrell et al. 2015; Urv and Parisi 2017). Results from these tests provide information for diagnosis, treatments, follow-up, and evaluation. Most the genetic testing performed for NBS is performed on mass spectrometry, which allows multiple conditions to be screened for at once. Traditional genetic testing, such as next-generation sequencing is not recommended as the initial technique for NBS, mainly due to the time taken to receive results (Berg et al. 2017; Ceyhan-Birsoy et al. 2017). Currently, researchers are exploring alternate DNA-based genetic tests to complement existing NBS methods (Friedman 2015).

Preimplantation and prenatal genetic testing

Genetic testing that determines if an embryo possesses genetic abnormalities prior to *in-vitro* fertilization is termed preimplantation genetic testing. This screening test decreases the chance of having a child with genetic abnormalities, since only embryos ‘passing’ the test are implanted into the uterus. Whole genome and exome sequencing are used to screen the embryos.

Another test, which examines genetic changes present within genes and chromosomes from a foetus is termed prenatal genetic testing. This test allows for detection of disorders such as Down’s syndrome and neural tube defect. Results from this test provide parents with information to prepare

for the child's care after birth, some parents choose termination of pregnancy. Novel testing methods have been evolving to detect genetic abnormalities, which include whole genome or exome sequencing (Vora and Wapner 2018). Measuring the cell-free DNA (cfDNA) from the foetus, which circulate in the mother's blood, serves as a form of non-invasive prenatal testing (NIPT) (Vora and Wapner 2018). NIPT whole genome or exome sequencing have also been reported (Fan et al. 2012; Kitzman et al. 2012), however, these techniques still possess a few limitations (i.e. cost of sequencing, limited cell-free placental DNA, and requirement of paternal DNA to determine the fetal genome).

Pathogen genomics

The use of genomics within pathogen detection, specifically infectious diseases, has made the greatest advances in genomics of public health. Advances in molecular technologies and bioinformatics have allowed researchers to examine pathogen genomes more rapidly, which has led to altering both medical and public health practice (Gwinn et al. 2019). Some of the public health applications for pathogen genomics, as described by the United States Centers for Disease Control and Prevention (CDC), are diagnosing infection, investigating outbreaks, describing transmission patterns, monitoring antimicrobial resistance, and developing interventions, including vaccines (CDC 2019). The CDC has an advanced molecular detection (AMD) programme that uses the latest technology to examine the key areas of pathogen genomics and has committed to making genomic data freely available. Access to pathogen genomic data is key to understanding pathogen mutations that could threaten public health, identifying new pathogens, development of diagnostic tests and determining and monitoring outbreaks (CDC 2019). Increasing the number of countries that subscribe to the data sharing model will dramatically improve pathogen genomics.

Next-generation sequencing is currently being used for pathogen genomics which provide rapid and reliable results compared to traditional clinical diagnostics. A new sequencing method, nanopore sequencing, has the potential to be the biggest game-changer for public health genomics. The first available commercial instrument has unrivalled portability (i.e. sequencing can be performed at any location, even from the outbreak site). This was demonstrated by studies that used nanopore sequencing in a

mobile genomics laboratory that travelled through rural Brazil monitoring the genetic diversity of Zika virus (Faria et al. 2017) and yellow fever virus (Faria et al. 2018). The sequences produced from these studies were analysed in real time, which allowed for the generation of pathogen diversity, distribution, and transmission data. Apart from the device portability, nanopore sequencing has a number of other benefits such as fast sample preparation, flexibility, long sequence reads, and relatively low cost. These benefits make this technology an attractive option as a first line strategy for pathogen sequencing in clinical and public health settings (Besser et al. 2017; Quainoo et al. 2017; Gwinn et al. 2019).

Technologies aiming to be implemented within a clinical health setting need to meet certain criteria in order to be fully utilized and provide public health benefit. Some of these criteria include, ease of use, cost-effectiveness, rapid results, minimized risk to patients, extended shelf life of reagents and the ability to function within resource-limited settings (i.e. interrupted electricity and extreme temperatures). The GeneXpert MTB/RIF test is one example where the technology has tremendous potential due to the ability to detect tuberculosis (TB) and the multidrug resistant form with very high sensitivity and specificity. However, this test does not meet some of the requirements to function effectively within a resource-limited setting, which has a large proportion of the TB infected patients (Evans 2011; Van Rie et al. 2011). It is therefore suggested that new technologies targeting diseases prevalent within resource-limited settings carefully consider the criteria to achieve maximum impact on public health.

Evaluation of genetic testing

Genetic testing is a rapidly expanding area with many clinical applications. As mentioned earlier the GTR (https://www.ncbi.nlm.nih.gov/gtr/), there are serval genetic tests currently being used around the world. While the introduction of new genetic tests creates tremendous potential for improving patient care, it is essential to evaluate these tests thoroughly to ensure that they are accurate and lead to improved patient outcomes when used in clinical practice settings. Therefore, methods have been developed to guide stakeholders (patients, clinicians, healthcare system policymakers, payers, and public health officials) in the assessment of tests, including

genetic tests, in a broad array of clinical settings. The process of implementing a molecular genetic test for diagnostic use is complex and involves many levels of assessment and validation. The key components of the process, as detailed by the ACCE framework, are analytical validation, clinical validation, clinical utility, and consideration of the ethical, legal, and social implications of the test (Pitini et al. 2018). Analytical validity and clinical validity are the two main measures of accuracy that apply to genetic tests. Another measure of the quality of a genetic test is its usefulness, or clinical utility (Holtzman and Watson 1999).

Analytical validity refers to how well the test predicts the presence or absence of a particular gene or genetic change (Teutsch et al. 2009), i.e. can the test accurately detect whether a specific genetic variant is present or absent?
Clinical validity refers to how well the genetic variant being analysed is related to the presence, absence, or risk of a specific disease (Teutsch et al. 2009; Wylie Burke 2014).
Clinical utility refers to whether the test can provide information about diagnosis, treatment, management, or prevention of a disease that will be helpful to a consumer (Teutsch et al. 2009; Wylie Burke 2014).

The Agency of Healthcare Research and Quality (AHRQ) report evaluated the four commonly used methods that cover the principal domains of test evaluation used in the environment of genetic testing. The four methods include; the US Preventative Services Task force (USPSTF) method (Harris et al. 2001; Trinite et al. 2009), the Fryback Thornbury hierarchy (Fordyce and Douglas 2017), the ACCE model and the Evaluation of Genomic Applications in Practice and Prevention (EGAPP) model (Teutsch et al. 2009). Framework such as Fryback–Thornbury hierarchy provide general conceptual guidance, analytic framework such as USPSFT and EGAPP provide additional benefit for important questions regarding the relevant population. A framework of interest was the McMaster University evaluation due to its thoroughness and richness in detail for making decisions about genetic testing (Giacomini et al. 2003). Also reviewed was the Genetic Testing Evidence Tracking Tool (GETT). GETT allows (1) researchers to summarize the current evidence and to identify knowledge gaps for further research, and; (2) stakeholders to collect data related to a

given molecular test and improve their decision-making process (Rousseau et al. 2010).

In the USPSTF method, the purpose is defined as preventive interventions in primary care. It provides a formal analytic framework; evidence assessment related to key questions to establish a chain of evidence. The downfall of focusing on preventive services results in a focus on clinical utility outcomes that are not relevant to all clinical applications (Sawaya et al. 2007). In contrast, the Fryback–Thornbury hierarchy, recognizes the clinical value of diagnostic efficacy and diagnostic thinking. It provides a hierarchic representation of levels of efficacy for medical tests, which allows an evaluator to determine what evidence types need to be assessed for a given test purpose or desired outcome (Morrison and Boudreau 2012). However, this method lacks a formal evidence-based assessment procedure. ACCE is an analytic process for evaluating evidence on genetic tests. It has a standard set of 44 questions that are organized according to different evidence types (analytic validity, clinical validity, clinical utility, ELSI) (Sanderson et al. 2005). This method provides a highly granular approach to assessing different evidence types. However, ACCE does not provide details on evaluating the strength of evidence. It was developed for single-gene tests and may be difficult to extend to multigene panels or genome-scale sequencing test. EGAPP has a systematic approach to evidence-based assessment of genetic tests (Teutsch et al. 2009).

A hybrid approach using analytic framework similar to USPSTF and the evaluation of evidence types articulated by ACCE might provide an enhanced method. The flexibility of this framework allows to evaluate different topics in genetic testing including a wide array of potential outcomes of interest, and integration of formal evidence-based reviews (Sanderson et al. 2005). The downside is the flexibility to evaluate different topics in genetic testing focus on single-gene tests that may be difficult to extend to broader genomic technologies. GETT provides structure for systematic identification and organization of published evidence on genetic testing. GETT comprises 72 clearly defined items/questions, grouped into 10 categories and 26 subthemes, including an overview of disease epidemiology and genetics, the available diagnostic tools, and their analytical and clinical performances, availability of quality control programmes, laboratory, and clinical best practice guidelines, clinical

utility, impact on healthcare, and psychosocial, ethical, and legal implications. The method helps stakeholders to determine whether the knowledge base is sufficient for genetic technology assessment (Rousseau et al. 2010). The disadvantage of this method is the lack of details on evaluating the strength of evidence; developed for single-gene tests and may be difficult to extend to multigene panels or genome-scale sequencing tests. The McMaster University framework is an evaluation model to guide public coverage for new predictive genetic tests in Ontario, Canada (Giacomini et al. 2003). This method combines technology assessment with coverage decision-making from payer's perspective. It defines criteria for determining coverage, anticipates the need for payers to identify evidentiary thresholds, and considers conditional coverage scenarios. Since it is developed for the Canadian health system, it lacks a formal evidence-based assessment procedure.

In order to achieve the full potential of genetic tests and to avoid inappropriate use, genomic tests need to be broadly understood and a dialogue between different types of clinicians, researchers, and drug companies needs to be facilitated. The frameworks mentioned earlier are intended to facilitate ongoing discussion and developmental activities among manufacturers, test researchers, systematic reviewers, regulators, and other policymakers. These discussions need to then facilitate understanding among clinicians and patients. Future frameworks should be broad enough to be applied to a wide variety of genomic testing. It is appreciated that the complexities and rapid advances within genomics (next-generation sequencing) and related fields (proteomics, metabolomics) will necessitate re-evaluating and tailoring frameworks over time.

Future aspects require examining patient outcome efficacy to determine if patients benefit from the test and if patients that take the test do better than similar patients who do not. Another aspect is observing at societal level, it should be noted that genetic testing should have a favourable effect on the health and allow effective health interventions throughout the entire population (Hall and Olopade 2005; Phillips et al. 2014). It is also important to examine ethical, legal, and social implications of genomic medicine (ELSI) and the effects of applying genetic technologies on a large scale (Clayton 2003). Technical efficacy for accurate detection of genetic variants, analytic, sensitivity, and specificity also include therapeutic and management efficacy as well as diagnostic thinking efficacy. This reflects a

useful synthesis of existing frame working efforts to date, it may allow more consistency in definitions for terms and concepts going forward and provide a platform for future collaborative efforts.

Pharmacogenomic testing

The combination of pharmacology and genomics has led to the new field termed pharmacogenomics, which essentially examines the effects a person's genes have on response to drugs. Tailoring effective, safe medications and doses according to the genetic makeup is one of the major goals of precision medicine. Most of the drugs currently available and being produced are designed as 'one size fits all', however, increasing evidence has demonstrated that drugs do not have the same effect on everyone.

Pharmacogenomics involves DNA and RNA influence on drug efficacy whereas pharmacogenetics only involves DNA and is usually observed for single genetic variants rather than a combination of variant effects. Pharmacogenomics is a relatively new field of research which is gaining momentum due to the variable effectiveness of drugs between individuals and it is an area of study that shows promise for the design of safe and efficacious treatments in a dose dependent manner according to an individual's genetic makeup (Roden et al. 2019). The majority of the drugs available today have been created without taking pharmacogenomics into account. These drugs have been created with a one drug fits all approach. Furthermore, many of the drugs that have passed clinical trials have been tested in mostly American/European Caucasians, some Asians, and a few individuals of African descent, therefore, extending these treatments to individuals from developing countries does not always prove successful. One of the major problems with using these non-tailored drugs are the adverse drug reactions (ADRs). ADRs occur at alarming frequencies and are well documented in developed countries. Most clinicians today use a trial and error approach when prescribing drugs. Usually, when an individual fails treatment due to ineffectiveness or the occurrence of a negative reaction the drug dosage is altered, or the drug is changed. This process is time-consuming, costly, and the potential of untimely death. In the US alone it is estimated that more than 100,000 individuals die from serious adverse events every year (Tan et al. 2016). Within developing

countries, it is estimated that death by ADRs greatly exceeds that of developed countries. This is mainly due to the genetic variation unaccounted for during drug development. The interindividual genetic diversity within individuals of African descent is several folds higher than other ethnic groups (Masimirembwa et al. 2014), which highlights the dire need for pharmacogenomic drug development within Africa.

Two major considerations should be considered when establishing whether a drug will prove efficacious in an individual, i.e. pharmacokinetics and pharmacodynamics. Pharmacokinetics is the process of absorption, transport to target site, metabolism, and excretion (Roden et al. 2019). Pharmacodynamics is variability in drug action that is not contributed by drug concentrations, and represents changes of the interaction of active drug with its effector molecules or other mechanisms such as variability in disease mechanisms (Roden et al. 2019). A large part of pharmacogenetic traits identified to date have a pharmacokinetic controlling mechanism.

Pharmacokinetic mechanism

There are two main scenarios that demonstrate how single gene variants affect pharmacokinetics that could lead to large effects. The first example requires the use of bioactivation pathways to achieve the desired therapeutic effects. Changes caused by mutations in the drug metabolizing enzyme can decrease or block the drug effect. An example includes codeine that gets bioactivated to active metabolite morphine with the *CYP2D6* gene (Roden et al. 2019). The majority of the variants identified offer partial or complete loss of function. There are fewer variants that lead to gain of functions within the bioactivation pathways, which subsequently leads to excess drug response. An example of gain of function variants include the *CYP2C19*17* that was linked to bleeding during clopidogrel therapy (Sibbing et al. 2010).

The second scenario is demonstrated when pharmacokinetic variants apply large effects during the administration of a drug that possesses a narrow therapeutic range of activity, that leads to either optimum activity or toxic doses. This is mainly through the elimination by a single drug metabolizing system. An example of this scenario is demonstrated by the antileukaemic drug 6-mercaptopurine that gets bio inactivated by thiopurine methyltransferase (TPMT) and xanthine oxidase. Individuals that are

homozygous for the loss of function variants within TPMT exhibit life-threatening bone marrow toxicity (Relling et al. 2019).

Transporter molecules, responsible for moving drugs into and out of cells, are affected by mutations that possess the capability of altering drug levels at target effector sites. An example of an efflux transporter gene that is affected by variants is the OATP1B1 encoded by SLCO1B1, which are shown to be variable in individuals of African descent (Naidoo et al. 2018; Naidoo et al. 2019).

Pharmacodynamics mechanism

Some of the initial well-described syndromes affected by pharmacogenetics are from the pharmacodynamics area. The anticoagulant drug warfarin is a well-studied pathway that acts by inhibiting the production of vitamin K dependent clotting factors in order to treat thrombotic disorders. The drug dosage is influenced by genes encoding the cytochrome P450 family (CYP2C9, CYP4F2, CYP2C) of enzymes responsible for the metabolizing the drug as well as a VKORC1 which recycles vitamin K in the body (Belley-Cote et al. 2015; Nagai et al. 2015). Testing for variation within these genes allow clinicians to make informed decisions when administering warfarin. If the drug is administered at a standard dose without testing for variation in these genes it may result in either too much drug in the bloodstream which can lead to excessive bleeding and death or not enough drug which could lead to thrombosis.

Another example can be observed during HIV treatment, where a combination of antiretrovirals are administered. One such drug known as abacavir has shown serious adverse reactions ranging from fever, nausea, vomiting, and death. Studies have shown that administering abacavir to individuals carrying the HLA-B*57 allele results in increased hypersensitivity and therefore testing for HLA-B*57 is recommended prior to administering abacavir (Sousa-Pinto et al. 2015; Illing et al. 2017). The allele frequency of HLA-B*57 in Caucasians is approximately 6% while in African Americans it is between 2% and 3%. However, in native Africans the allele frequency is much lower. Another HLA-B allele (HLA-B*15:02) has also shown an effect on Stevens–Johnson syndrome and toxic epidermal necrolysis (SJS/TEN). HLA-B*15:02 confers risk of the disease mainly

within southeast Asian populations, in which the allele is found in relatively high frequencies (Chung et al. 2004). However, a different HLA allele (HLA-A*31:01) has been linked to the SJS/TEN disorder within individuals from European ancestry (McCormack et al. 2011). These studies reporting differing alleles contributing to SJS/TEN highlights the need to examine the genetic profiles for each population the drug is being administered to. However, there is much controversy about whether enforced HLA-B*15:02 testing is cost-effective (Rattanavipapong et al. 2013; Chong et al. 2017). The implementation of a testing campaign, within Hong Kong that examined more than 100,000 patients, showed a decrease in the prescription of carbamazepine and a decrease in related SJS/TEN (Chen et al. 2014). However, the prescription of other antiseizure medications increased in this study and examining this group showed no overall change in SJS/TEN (Chen et al. 2014). The authors report, clinicians preferring antiepileptic drug (AED) therapy that do not require genetic screening are preferred, this exemplifies the need for educational programmes to supplement the implementation of testing programmes.

An example of the type of infecting organism found within a person also plays a role on the type of drug administered. Maraviroc, an HIV drug that binds onto the HIV entry receptor, CCR5, prevents the virus entering into the cell for viral replication. However, the desired effect of maraviroc is achieved within individuals that possess only the CCR5 receptor strain of HIV. The virus also uses CXCR4 to enter into the cell. Maraviroc does not function with CXCR4 strains of HIV, therefore, health providers need to determine the receptor usage before prescribing the drug (Ryst 2005).

Pharmacogenomics and drug development

A huge amount of effort and resources goes into the development of drugs to treat a range of diseases and disorders, however, the number of drugs candidates entering clinical trials are very small in number. Increasing evidence suggests that studies examining the human genetic components of the drug have an increased likelihood of successful marketing than those drugs not testing the genetics (Sanseau et al. 2012; Nelson et al. 2015; Zhang et al. 2015). Drugs that have proved to be successful in clinical trials still have remarkable failure rates when these drugs are given to the target

audience. Since most of these trials are being performed in developed countries and do not take into account the genetic effect on individuals from underdeveloped countries not knowing the human genetics within these populations hinders the desired effect of the drug.

Ideally, when a drug is created for an individual or individuals within a population, their genetic diversity must be considered. Since the assembly of the first human genome there has been an explosion in the generation of genomic data with projects providing full length whole genome sequences that are curated and annotated. Using this data, there is evidence that the haplotype frequency and overall genetic diversity is much higher in Africans than Caucasians and Asians (Rotimi et al. 2017). Furthermore, within Africans there is an additional spread of genetic diversity which suggests that drugs need to be designed for specific populations. For example, a drug created to treat African individuals from Northern Africa should be reconstructed to treat African individuals in Southern Africa due to their genetic differences. In regions where there is minimal diversity, genetic screening can be used to test whether a drug is suitable for that candidate.

Currently, there are a number of platforms that offer the ability to test the suitability of a drug. The cheapest and smallest scale screening is the genotyping approach which works using polymerase chain reaction (PCR) technology to determine the presence of single variants. This can be used when a single SNP has an effect on drug efficacy. Another approach is the use of genome-wide association study (GWAS) to identify the variants carried by an individual. This test provides a more comprehensive picture than the single variant genotyping. Special chips can be designed to suit a specific population or trait. WGS provides the maximum genomic information for an individual. Patients who screen their whole genome can be assessed not only for genetic variants that alter drug efficacy but also a myriad of information such as their susceptibility to infectious diseases as well as the likelihood of developing heritable diseases.

Pharmacogenomics is a step in the direction towards precision medicine and may help to reduce the burden of disease by improving outcomes with specialized drugs. The epigenome has been shown to have a significant effect on gene regulation and interactions between the genome and epigenome may provide an additional layer of complexity to the field of pharmacogenomics. The use of WGS and whole genome methylation in

conjunction with pharmacology will allow us to understand much more about the landscape for treating disease.

Epigenetic therapy

The field of epigenetics has rapidly expanded in the past few decades to the extent that novel forms of therapy are emerging from this field that warrant discussion in this chapter. It is well established that epigenetic changes contribute to the development of human diseases such as cancer, autoimmune disease, as well as neurodegenerative and psychological disorders (Hahn and Weinberg 2002; Jones and Baylin 2002; Zoghbi and Beaudet 2016). Epigenetics refers to all heritable alterations in gene expression and chromatin structure due to chemical modifications that do not involve changes in the primary nucleotide sequence (Strahl and Allis 2000; Jenuwein and Allis 2001; Nightingale et al. 2006; Bernstein et al. 2007). Epigenetic mechanisms have the ability to either appropriately regulate cell growth (Portela and Esteller 2010; Moosavi and Motevalizadeh Ardekani 2016) or in contrast, dysregulation of epigenetic patterns lead to induction and propagation of disease states (Hahn and Weinberg 2002; Jones and Baylin 2002; Feinberg et al. 2006).

There are several factors that contribute to epigenetic alterations, the factors with the strongest contribution include DNA methylation, histone modifications, and non-coding RNAs. All of these are crucial mechanisms that ensure the stable propagation of gene activity from one generation of cells to the next (Jenuwein and Allis 2001; Feinberg et al. 2006). Disruption of any of these three distinct and mutually reinforcing epigenetic mechanisms leads to inappropriate gene expression, resulting in cancer development and other ‘epigenetic diseases’ (Jones and Baylin 2002; Egger et al. 2004; Feinberg et al. 2006). In some instances, pathogens have been able to take advantage of epigenetic alterations for their propagation.

In recent years, scientific interest in epigenetics has increased substantially so that this field represents an important new avenue to advance our understanding of pathogenesis and to help in the development of strategies for disease. It is hoped that by understanding epigenetic mechanisms effective therapies would soon become available. Epigenetic therapy, a relatively new outlook to treatment, involves the use of drugs or

epigenome altering tools to change the non-DNA environment to treat medical conditions. There are about 191 clinical trials around the world involving epigenetic therapy, according to the NIH clinical trials database, indicating the potential of this rapidly growing field (NIH 2019). Most of these clinical trials have targeted different forms of cancer, however there are several other diseases which also have been targeted. Drug reposition efforts have been launched to explore epigenetics therapies for non-oncology conditions (Best and Carey 2010). Some of these conditions include diabetes mellitus, depression, rheumatoid arthritis, schizophrenia, etc.

Clinical conditions treated with epigenetic therapy

DNA methyltransferase (DNMT) enzymes are responsible for the addition of methylation to DNA, these enzymes are inhibited with the drugs 5-azacytidine and 5-aza-20-deoxycytidine. Both drugs have been approved for use by the FDA for the treatment of various forms of cancer. These drugs have been shown to reactivate the cellular antitumor systems repressed by the cancer, enabling the body to weaken the tumour (Foulks et al. 2012; Vendetti and Rudin 2013; Li et al. 2014; Wells et al. 2014). Zebularine, an activator of a demethylation enzyme, has also been used with some success (Kowluru et al. 2013). The wide-ranging effects of these drug on the entire genome may result in major side effects, however, survival rates are significantly increased when the drugs are used for treatment.

The largest class of epigenetic therapies is inhibitors of histone-modifying enzymes. These include drugs that inhibit histone methyltransferases (HMTs) and histone deacetylases (HDACs) and are the most prevalent form of epigenetic therapy. In addition, there are several compounds that activate HDACs or inhibit HDMs, currently being developed. These include inhibitors of the H3K79 methyltransferase DOT1L for the treatment of Mixed-lineage leukaemia (MLL)-rearranged leukaemias (Barski et al. 2007). The treatment of non-Hodgkin lymphoma involves the inhibitors of the H3K27 methyltransferase EZH2, which form the catalytic component of the PRC2 complex (Bradley et al. 2014). Use of HDAC inhibitors, specifically HDAC6, are being explored for the treatment

of certain cancers such as multiple myelomas and a wide variety of haematologic malignancies (Li et al. 2018). Epigenetic therapy also includes the use of bromodomain and extraterminal motif (BET) bromodomain inhibitors. Bromodomains are evolutionary conserved protein-protein interaction modules that preferentially recognize acetylated chromatin (Fujisawa and Filippakopoulos 2017). The use of BET bromodomain inhibitors that possess broad binding specificity have been tested for treatment of advanced haematologic and non-haematologic malignancies (Sanchez and Zhou 2009).

Treatment of diabetic retinopathy using epigenetic therapy has also been explored. One therapeutic approach includes inhibition of methylation within manganese superoxide dismutase (SOD2) and matrix metalloproteinase (MMP-9). The DNMT inhibitors 5-azacytidine and 5-aza-20-deoxycytidine inhibit the SOD2 and MMP-9 methylation patterns and have been reported to reduce diabetic retinopathy symptoms (Kowluru et al. 2013). Limited success has also been reported for the treatment of this disorder with histone acetyltransferase (HAT) inhibitors epigallocatechin-3-gallate, vorinostat, and romidepsin (Kowluru et al. 2013).

The epigenetic mechanisms of lupus have been studied in detail, which has assisted the use of epigenetic-based therapies into clinical trials against lupus. A cytidine analogue, Cytarabine, reported to increase DNA methylation, was used for treatment of refractory cutaneous lupus in a human clinical trial (Mishra et al. 2003). Results showed relapse of disease during the fourth week in two-thirds of tested cases, however, treatment with Cytarabine also showed rapid improvement of refractory cutaneous lupus in treated patients (Yung and Richardson 1995).

There have been many experimental drugs that target epigenetic mechanisms against rheumatoid arthritis (RA). DNMT inhibitors such as 5-azacytidine was used to treat normal synovial fibroblasts and this reproduced RA synovial fibroblasts phenotypes (Kooistra and Helin 2012). Trichostatin A (TSA) and nicotinamide, both HDAC inhibitors, were separately used to reduce TNF-α which in turn reduces IL-6 expression in macrophages isolated from PBMCs of RA patients (Gillespie et al. 2012). Other studies have shown that targeting HDACs, using HDACi such as valproic acid, can mitigate the severity of murine chronic inflammatory arthritis in part via improving regulatory T-cell function (Chung et al. 2003; Saouaf et al. 2009). These show potential therapeutic value, due to their

ability to reduce or disrupt the production of inflammatory signals that fuel RA disease activity. Another promising study silenced SIRT1 and promoted apoptosis in RA synovial fibroblasts from synovial tissues and cells from RA patients (Niederer et al. 2011).

Multiple sclerosis (MS) is another clinical disorder for which investigators have considered epigenetic therapy for treatment. Histone deacetylases inhibitor, such as TSA, has reduced spinal cord inflammation, demyelination, neuronal and axonal loss in experimental autoimmune encephalomyelitis (EAE) models, and thus serves as a potential treatment option for MS (Camelo et al. 2005). However, HDAC inhibitors used at the systemic level have shown to negatively affect the generation of new myelin, since HDAC is crucial to developmental of myelination (Marin-Husstege et al. 2002; Shen et al. 2005). Chirivi et al. have proposed citrullination as a target for epigenetic intervention in MS and other inflammatory diseases (Chirivi et al. 2013). The authors also postulate that shielding citrullinated histone epitopes, which play a large role in NET formation, can help prevent the intensification of the inflammatory response in MS and other inflammatory diseases (Chirivi et al. 2013).

Advantages and disadvantages of epigenetic therapy

Unlike genetic defects, epigenetic defects are potentially reversible and are therefore more amenable to corrective therapeutic reversal. This realization has driven the rapid emergence and expansion of epigenetic drug discovery, and drug-targeting epigenetic enzymes are in the clinic for the treatment of human disorders, especially for clinical management of haematological malignancies and neurological disorders. However, treatments with epigenetic drugs still need to overcome the challenge of avoiding off-target effects. It should be considered that multiple epigenetic enzymes are contained in chromatin complexes, and as a result the inhibition of an epigenetic enzyme can result in changes in other members of the same protein complex. For example, treatment with the HDAC inhibitor sodium butyrate alters the acetylation level of histones, but also affects their methylation status. In addition, drug development based on epigenetics is difficult and expensive similar to other drug targets.

Epigenomic technologies

Similar to GWAS, epigenome-wide association studies (EWAS) could be a diagnostic tool for screening epigenetic disorders. An EWAS is an examination of a genome-wide set of quantifiable epigenetic marks, such as DNA methylation, in different individuals to derive associations between epigenetic variation and a particular identifiable phenotype/trait (Flanagan 2015). Bisulfite conversion is used for the detection of DNA methylation levels, methylated cytosines are saved from conversion to uracil and thus measured using WGS. Whole genome and RNA sequencing are valuable tools for the screening of non-coding RNAs. Continued study of genome sequences can help determine whether new genetic variations are associated with health conditions.

Epigenetic therapy in the future

Future studies may be able to identify methods for recognition response mechanisms by combining genomic sequencing and gene expression profile. In addition, DNA could also undergo histone modifications, phosphorylation, ubiquitination, sumoylation, and acetylation. Each of these mechanisms could provide novel opportunities for epigenetic therapies in the future. The use of non-coding RNA (ncRNA) is also an avenue that is currently being explored. MicroRNAs (miRNA), a class of ncRNA, that are about 19–24 nucleotides long, prevent the translation of mRNA and protein production (Nam et al. 2009). As miRNAs play critical roles in regulating functions of the cells, disruption in their structure and turnover can cause diseases. There are 651 miRNA clinical trials reported on the NIH clinical trials database (NIH 2019) highlighting the growing interest of this avenue for treatment of clinical disorders. The use of specific miRNA mimics and inhibitors that modulate miRNAs and regulate gene expression could be an attractive avenue for future research. miRNA mimics have shown therapeutic benefit in mouse models of lung cancer (Trang et al. 2011; Kasinski et al. 2015). Therapeutic delivery was demonstrated using mimics of the tumour suppressors, microRNA-34a (miR-34a) and let-7, both of are often downregulated in lung cancer. Specifically, mice treated with miR-34a displayed a 60% reduction in the tumour area compared to mice treated with a miRNA control (Trang et al. 2011). Similar results were obtained

with the let-7 mimic. As a single miRNA may be able to target more than one gene it would be interesting to combine several microRNA with different targets so that various proteins involved in different steps of a disease can be regulated, enabling a combinatorial, multitarget approach that could complement combination drug treatment.

Long non-coding RNA (lncRNAs) should be taken into account as future advances in epigenetic therapy, since lncRNAs could also be regulated by epigenetic mechanisms, including CpG methylation as well as histone marks (Kung et al. 2013). They are involved in chromatin remodelling, as well as transcriptional and post-transcriptional regulation, through a variety of chromatin-based mechanisms and via cross-talk with other RNA species (Zampetaki et al. 2018). There are currently 32 clinical trials for lncRNA according to the NIH clinical trials database (NIH 2019). The data gathered so far concerning the involvement of lncRNA in epigenetic regulation is still the tip of the iceberg of this emerging field, and further expansion of these data may reveal untapped targets and pathways amenable to epigenetic therapy. In addition, as mentioned earlier, screening for epigenetic diversity across diverse populations prior to administering epigenetic therapies will assist with the success of the treatment.

Genome editing and public health

Genome or gene editing provides the ability to edit an organism's genetic material to achieve a desired trait. Using genome editing technologies researchers can modify precisely specific additions, deletions, and alterations to specific sites within the genome. There are several tools used for genetic editing, however since the advent of clustered regularly interspaced short palindromic repeats (CRISPR) there has been much excitement. The reason for the excitement is mainly due to CRISPR being faster, cheaper, increased in accuracy and efficiency when compare to the existing genome editing methods. Some of the common methods used prior to the arrival of CRISPR include meganucleases, zinc fingers nucleases (ZFNs), and transcription activator-like effector nucleases (TALENS).

Meganucleases

These are endonuclease molecules, also called homing endonucleases, that can be grouped into five families (Pingoud and Silva 2007). The large recognition site, that is rarely found within an entire genome, allows this tool to function highly specifically for the editing of genomes. The meganucleases carry the genetic portion that influences recombination during homing (Orlowski et al. 2007). Meganucleases have been implemented in an industrial scale to target research, bio-manufacturing, bio-production, and have a potential role in human healthcare. A limitation of this tool is that small sequences that may play a role in disease outcome are not targeted.

Zinc finger nucleases (ZFNs)

ZFNs are fusion proteins that have been adapted from zinc finger containing transcription factors, which possess numerous site-specific DNA-binding domains. These fusion proteins are linked to the bacterial FokI restriction enzyme, which forms the endonuclease domain (Gupta and Musunuru 2014). A single zinc finger domain possesses the ability to recognize and bind a 3- to 4-bp DNA fragment, the combination of domains allows for the ability to detect a large target DNA sequence. Cleavage of a site in the DNA sequence is bi-directional using two flanking sequences. Once the ZNFs are bound at a specific site in the genome, the two FokI domains dimerize and cuts the DNA, which generates a double stranded break (Urnov et al. 2010; Gupta and Musunuru 2014). A major limitation of this tool has been found to be the off targets effects. For a more precise edit, more zinc finger domains are required, which increases costs of the application (Urnov et al. 2010).

Transcription activator-like effector nucleases (TALENS)

This endonuclease has a similar mechanism of action to ZFN. However, instead of ZFN binding to three nucleotides (codon), each nucleotide has its own zinc finger protein (33 to 35 amino acids), which are much larger than ZFNs (Gupta and Musunuru 2014; Miller et al. 2010). In addition to the length advantage, TALENS are also easier to design and have fewer constraints of site selection than the ZFNs. Limitations of TALENS is the large size and their highly repetitive nature (Gupta and Musunuru 2014).

CRISPR-Cas9

CRISPR is a gene editing tool based on the bacterial adaptive immune system. Bacterial cells retrieve protospacers from invading bacteriophages and incorporates them within their genomes. These protospacers are then used as short guide RNAs by a CRISPR-cas system and target any foreign DNA possessing the matching incorporated protospacer sequence. The invading DNA is cut using the cas9 enzyme, which enables cutting of the double stranded DNA. The CRISPR-Cas9 currently being used in research labs is mimicked from the bacterial system (Hsu et al. 2014). Several versions of a modified Cas9 protein exists, which enables CRISPR gene editing system to be the most versatile and precise tool on the market.

CRISPR-based clinical trials

CRISPR has the potential to be used as an editing tool for genetic diseases. Recently, a group of scientists produced CRISPR engineered mouse pluripotent stem cells, which are resistant to proinflammatory cytokines. Not only do these engineered cells prevent inflammation, they also alleviate inflammation in chronic inflammatory diseases such as arthritis (Brunger et al. 2017). In 2018, the mutated *DMD* gene, which causes Duchenne muscular dystrophy, was edited in dogs using the CRISPR-Cas9 system and delivered using an Adeno-associated virus. As a result of CRISPR-Cas9 mediated editing, dystrophin expression was restored in a canine model of Duchenne muscular dystrophy (Duan 2018).

Following the success of CRISPR as a therapy against disease in animals, many human clinical trials against various diseases have been initiated. According to the NIH clinical trials database (www.clinicaltrials.gov), a total of 28 CRISPR-based clinical trials are underway by multiple groups targeting a range of diseases including HIV-1 and other viral infections, sickle cell disease, thalassemia, Kabuki syndrome, Leber congenital amaurosis (blindness), malignant hyperthermia, various leukaemias and lymphomas, as well as various cancers (NIH 2019).

Interest was sparked in 2016, the first phase I pre-clinical trial involving CRISPR gene editing technology in cancer research in China, as well as the second CRISPR initiative in the treatment of two debilitating inherited blood disorders, beta thalassemia (TDT) and sickle cell disease (SCD), both

in the United States and by the Swiss (Baylis and McLeod 2017; Nasdaq:CRSP 2019). Currently, these two CRISPR trials are being approved to edit immune cells against tumours and to activate genes that are inactive, making these the initial two out of several human trials that are underway. These treatment approaches may become a novel and powerful therapeutic intervention against various other diseases as well.

The trial entitled CTX001-121 aims to treat various hemoglobinopathies such as severe SCD and thalassemia. The first patient to be treated with the CTX001 drug had a form of thalassemia. Following treatment, the patient reportedly did not require any blood transfusions (the usual treatment for thalassemia) for 4 months. The first patient with severe SCD was also treated with CXT001 in 2019 (NIH Clinical Trials 2019). There are also plans by the companies behind this trial to run gene therapy trials on patients suffering with Duchenne muscular dystrophy (DMD) and myotonic dystrophy type 1 (MD1) (Wang et al. 2018).

In addition to CRISPR, the FDA has approved other gene-based therapies to treat an array of diseases. These include (1) Luxturna, used for the treatment of a different form of Leber congenital amaurosis (blindness—retinal dystrophy) (Maeder et al. 2019); (2) Zolgensma, approved for the treatment of SMA, a leading cause of infant mortality (Pena et al. 2020); and iii) Kymriah, which is an approved cell based therapy for the treatment of some blood cancers such as acute lymphoblastic leukaemia (ALL) (Montano et al. 2018).

CRISPR's potential to hit drug markets as a prescribed therapy against not only genetic but also against infectious diseases is huge. HIV is one infectious disease that has been targeted by CRISPR technology. Using the Cas9/sgRNA parts of the HIV genome was targeted for cleavage in an attempt to decrease the replication of the virus, however, the virus was able to overcome CRISPR editing by escape mutations located within the cas9 cleavage site of the virus (Wang et al. 2016a, b). The therapeutic potential of CRISPR needs further exploration and it is estimated within the next few decades the genome editing tool will play a major role in personalized and public health.

Advantages and limitations of CRISPR

The important advantage of the CRISPR Cas9 system over other gene editing technologies is the simplicity, cost-effectiveness, and efficiency. In addition, the technology has the potential to be applied directly to embryos to modify target genes, which enables rapid desired affects when compared to alternative gene editing technologies that require use of embryonic stem cells. Another benefit of the CRISPR system is the improved bioinformatic tools that are available to design guide RNAs. Optimizing of experimental conditions is simple and robust, which almost guarantees introduction of the desired edit will be successful. Furthermore, CRISPR can edit virtually any genome, this provides it with the capability to treat diseases, destroy infecting microorganisms, resurrect species, and create healthier foods without the use of antibiotics (Omodamilola and Ibrahim 2018). Additionally, the CRISPR tool proves to be far superior to competitors, due to its ability to modify multiple genes in a single experiment, up to 25 targets have been reported successfully (Campa et al. 2019). CRISPR possesses yet another benefit over competing gene editing technologies with its ability to alter the epigenetic environment. This is achieved by using a deactivated form of the cas9 protein, which does not cut or edit the DNA sequence but instead changes the surrounding epigenetic environment with accessory molecules attached to deactivate cas9 (Bae et al. 2019).

One of the main limitations of the CRISPR technology is the off-target effects. The guide RNA, which is intended to bind onto a specific target may also bind on other unintended sites resulting in unplanned altering or deactivating of genes, thus producing side effects. The simplicity of the CRISPR tool may also be its downfall, questions about the tools ability to create bioweapons or designer babies are raising significant ethical concerns.

Ethics of CRISPR

The CRISPR technology received a significant amount of negative attention from November 2018, after the first human babies created from edited embryos were revealed to the world by the Chinese scientist, Dr Jianku He. This sent the scientific research community into debates regarding the ethical, legal, and social implications regarding the germline editing (Kleiderman and Ogbogu 2019). The research has violated Chinese regulations and international bioethical standards. The Chinese regulations

on gene editing seem to align with international standards (Isasi et al. 2016; Kleiderman and Ogbogu 2019). In addition to the ethics concerns of the 'CRISPR babies' experiment, researchers have also questioned the soundness of the research conducted. The gene targeted for editing, CCR5, is required for viral entry only for the CCR5 strain of the virus, however the CXCR4 viral strain can still be transmitted despite altering the CCR5 gene. There is currently a drug, maraviroc, against CCR5 that has been used in numerous HIV clinical trials. Individuals with mutated forms of CCR5 have an increased risk of symptomatic West Nile virus infection (Glass et al. 2006). These events have certainly created more focused attention on human genetic editing, despite this study not being the first to edit human genes in an embryo (Bonora et al. 2015). Researchers in 2015, reported CRISPR/Cas9-mediated editing of endogenous beta-globin gene in human embryos (Liang et al. 2015). The authors also reported unplanned off-target effects as determined by whole exome sequencing and cautioned the pressing need to further improve the fidelity and specificity of the CRISPR/Cas9 platform (Liang et al. 2015).

Any future clinical trials aiming to alter human embryos should be subject to much discussion, especially for the need of such an experiment. Due to the simplicity of the technique, potential to leap into the public platform, and the convincing potential applications, it probably wouldn't be too long before another unorthodox individual announces the results of their human embryo editing experiments.

The US National Academy of Sciences and the National Academy of Medicine constituted a multidisciplinary, international committee to review the current status and make recommendations based on the ethical concerns raised (Coller 2019). The report makes recommendations, which include experimental germline genome editing that is subject to restrictions that include research focused on preventing transmission of a serious disease or condition, modification of well-documented DNA changes associated with disease, and research conducted under a set of stringent ethical and regulatory guidelines (Coller 2019). However, with simplicity of use and easy accessibility, mail-order do-it-yourself CRISPR kits are currently available for a few hundred US dollars, experts are concerned about what amateur scientists may achieve with the powerful tool (Sneed 2017). Is the world ready to implement such strategies or should CRISPR remain in a laboratory setting until future stable gene editing techniques are developed?

There is also the growing concern of CRISPR being used as a biotechnological threat (Vogel and Ouagrham-Gormley 2018). This technology can make a treatable pathogen become deadly by altering the drug target sites.

Another major concern is, if CRISPR germline editing eventually becomes regulated and allowed in the future, who will the technology be accessible to? Will it simply be for the rich and famous? The main challenge for nations experimenting with gene editing is to come up with feasible, rational, and ethical guidelines for its practical implementation. CRISPR is still a developing technology, which provides a strong foundation for the development of new advanced tools in the field of gene editing.

Ethical implications of genomics and public health

The rapid advances in the field of genomics and public health arises with a new set of ethical problems that need to be addressed. A framework by Burke et al. highlights several important aspects of improved population health (Burke et al. 2006). These include engaging with a range of stakeholders that are within and external to the public health and scientific communities. The aim is to provide a support of core activities, some of these include; advising on public policy; design, implementation, and evaluation of preventive and clinical health services; communication and stakeholder engagement; and finally dissemination of knowledge via education and training (Burke et al. 2006). Roberts and colleagues have reviewed in detail some of the emerging issues in public health genomics (Roberts et al. 2014). We provide an updated summary of these emerging issues in this chapter.

Informed consent

Genomic testing can provide specific confirmation or diagnosis as described earlier, however in certain instances genomic testing may raise more questions, i.e. some tests may not provide meaningful information within the present setting. However, after ongoing interpretation of the results, researchers may find relevant information in the future, therefore

the informed consenting process needs to be adequate to deal with these wide range of outcomes (Horton and Lucassen 2019). Several researchers believe we are not achieving valid consent in the genomic setting, since the consent to be valid 'the patient needs to be competent; they need to be appropriately informed; and their consent needs to be voluntarily given' (Horton and Lucassen 2019). The process of informing a patient appropriately means possessing a clear understanding of the genetic results obtained, this is in most instances not the case. Even within experts in the field, as demonstrated by the APOE status of Dr James Watson, one of the first people to be sequenced. He released his sequenced genome to online public databases, except for apolipoprotein E (ApoE), which was redacted due to its linkage with Alzheimer's disease, Dr Watson preferred not to know his status (Nyholt et al. 2009). However, based on linkage information found throughout the rest of the genome, the Alzheimer's information could be ascertained. The linkage information located in other parts of the genome was only discovered later (Nyholt et al. 2009; Horton and Lucassen 2019). Does this mean the informed consent was violated? If so, what could have been done to better protect Dr Watson? These are some of the questions that should be asked in future when achieving consent in the genomic setting. Dr Watson's case is just one of many scenarios where public health genomics have left patients with undesirable outcomes. Patients who participate in genomic research should also be informed of both the risks and benefits of testing (Department of Health et al. 2014; Miller et al. 2008).

Prenatal screening

Within the United States alone, nearly all the 4 million infants born a year are screened for rare genetic diseases (Roberts et al. 2014). Genetic screening has enabled parents to make informed choices regarding the welfare of their child's health. Testing for Down's syndrome is especially common in pregnant women over 50 years of age as there is an increased risk of non-disjunction during meiosis resulting in ova that could lead to the birth of a child with Down's syndrome (Reynolds 2003; Dukhovny and Norton 2018). Some of the symptoms of Down's syndrome include learning disabilities, stunted or delayed growth as well as characteristic facial features, however, many of the more serious health problems associated

with this disease can be treated. The life expectancy of children with Down's has increased dramatically as there is now reduced stigma and better healthcare available. Genetic testing provides the ability for a positive Down's syndrome infant to be treated earlier, however, certain parents choose the option of premature pregnancy termination (Dukhovny and Norton 2018). As the number of prenatal genetic tests become available, there needs to be a balance of autonomy and distributive justice (Dukhovny and Norton 2018).

Data storage and sharing

Sharing of genomic data has become an actuality with the advent of genomic databases that allow access to thousands of whole genome sequences for the purpose of scientific advancement (Mathaiyan et al. 2013; Dijkers 2019). At the point of data collection, is the participant privy to their own information? Does that information remain within the institute or is it shared with other institutes or companies? As WGS becomes more affordable the risk of data sharing with employers and health insurances or medical aids becomes a potential problem. If an individual who works in a laborious field is predicted to develop Parkinson's, sensitive information such as this may lead the employer to retrench him/her due to this information. Additionally, information like this may cause their insurance premiums to skyrocket or medical aid be denied or delayed. Access to such sensitive data can lead to its abuse allowing government, employers, and companies to exploit individuals (Dijkers 2019).

The need for confidentiality cannot be disputed when performing genomic research. The genetic data from WGS gives important information about current or potential diseases as well as risk of disease. In the case of rare diseases, it may be easy for the identity of the patient to be leaked because of the rarity of the disease itself (Dijkers 2019). The breach of confidentiality could expose the individual to discrimination in the workplace as well as in social settings. Proper channels for blinding patient data are necessary similar to what is performed during clinical trials, however, there needs to be additional measures to ensure that there is no leak in data.

Storage of samples

Biological specimens can be frozen for many years at a time. Researchers use these samples to answer many questions and may store them for use in future studies. Indefinite storage of samples means that the research being conducted on these samples will never end (Vaz and Srinivasan 2014). Although consent may be given by the participant for a particular study or overall type of study there is no definite way for them to know what will be done on the samples in the future (McGuire and Beskow 2010). Generally, when consent is given there is very little a patient can do regarding the studies being performed on their samples. Considering the stability of DNA, these risks to privacy of genetic and personal information does not decrease with time. Considering the long-term storage and dissemination of samples, should researchers constantly request updated consent, where the patient is informed of new or ongoing studies and recompensated (Haga and Beskow 2008)?

Conclusion

The field of public health genomics has been growing rapidly over the past few years and is projected to increase steadily in the future. The significant improvement of new technologies has made genomics accessible within the public health setting. An explosion of genetic tests examining conditions that range from several rare diseases to a variety of common diseases have started to reach the market. Caution should be implored when a new genomic test reaches the market. Each test needs to meet certain diagnostic requirements within a target population before it is implemented as a genomic test within the public health sector. In addition, pharmacogenomics testing is encouraged before a new drug is administered within diverse ethnic groups.

Advancements in the field of epigenetics has led to new therapeutic treatment options against a range of conditions. Epigenetic therapy is in its early stages and has enormous potential for future applications. Despite setback within the field, gene therapy is still argued to be the treatment of the future. Significant policies and ethics guidelines are required to be reviewed and implemented for gene therapy to be utilized as a therapeutic tool in the future. Public health genomics is an exciting area that can benefit

a larger segment of the population by bringing the right interventions to the right population at the right time.

2.7

Water and sanitation

Thomas Clasen

Introduction to water and sanitation

Background

Safe drinking water and sanitary waste disposal are among the most fundamental of public health interventions. When readers of the *British Medical Journal* were asked in 2006 to name the 'greatest medical advance' since 1840, their top choice was clean drinking water and waste disposal, beating antibiotics, anaesthesia, vaccines, and germ theory (Ferriman 2007). Deaths from diarrhoeal diseases and typhoid fever showed dramatic declines in Europe and North America when cities and towns began filtering and chlorinating their water and safely disposing of human and animal excreta (Cutler and Miller 2005). The field of epidemiology arguably has its origins in John Snow's nineteenth-century mapping of cholera cases and the eventual intervention at London's Broad Street pump that demonstrated waterborne transmission of the disease.

While diseases associated with poor water and sanitation are now comparatively unknown in higher-income countries, they still impose a heavy burden elsewhere, especially among young children, the infirm, the poor, the immunocompromised, and the displaced. Diarrhoeal diseases alone are responsible for an estimated 1.3 million deaths annually, including a half million children under 5 years (Troeger et al. 2017). Diarrhoea is the third leading cause of deaths of children <5 years in low-income countries, accounting for 11% of the overall disease burden in this population. Improvements in water, sanitation, and hygiene have the potential to reduce this disease burden by an estimated 58% (Prüss-Ustün et al. 2014). As discussed next, poor water and sanitation is also associated with a heavy disease burden from malnutrition, parasite and worm infection, trachoma, and environmental enteropathy. Water and sanitation are not only a matter of public health, but also of poverty, equity, and justice (United Nations Development Programme 2007). Because they are less likely to have access to safe water and sanitation, the poor bear most of the burden of water-related diseases, driving them further into poverty through lost productivity and expenditure on treatment

(Blakely et al. 2005). Time spent in collecting water from distant sources and the inability to procure sufficient quantities of water for irrigating crops, watering animals, and carrying out other productive activities aggravates poverty. While urban-rural disparities in water and sanitation coverage are well documented (WHO and UNICEF 2017), a recent analysis of sub-Saharan Africa also demonstrated important geographic inequalities in use of water and sanitation previously hidden within national statistics (Pullan et al. 2014). These results confirm the need for targeted policies and metrics that reach these marginalized populations (Pickering and Davis 2012). Inadequate water and sanitation are also associated with poor cognitive development and school attendance (Sclar et al. 2017). For these and other reasons, water and sanitation have been recognized as a fundamental human right (United Nations 2010).

Nevertheless, basic water security and sanitation still elude much of the world's population living in low-income countries. An estimated 582 million people still lack improved drinking water sources; hundreds of millions more rely on water that is not safely managed (WHO and UNICEF 2017). An estimated 2.3 billion people—30% of the world's population—lack access to improved sanitation; 892 million still practice open defecation. Coverage is lowest in developing regions, where people are most vulnerable to infection and disease. In sub-Saharan Africa, safely managed or basic water and sanitation coverage is just 42% and 28%, respectively. Rural areas also lag behind their urban counterparts. In 2015, 85% of urban populations had access to safely managed drinking water; whereas only 55% of rural populations had access. If current trends continue, people in rural areas will only account for one-third of those who have access to water free from contamination (WHO and UNICEF 2017).

The shortfall in water and sanitation coverage is not the result of a failure to recognize the need or declare goals at the highest international levels. The 1977 Mar del Plata Declaration by the United Nations (UN) expressed the goal of providing safe water and sanitation for all by 1990, launching the Water and Sanitation Decade (1981–1990) (Cairncross 1992). In 1990, the UN renewed the call and extended the deadline to the end of the century. The UN Millennium Development Goals (MDGs) call for halving, by 2015, the portion of the population without sustainable access to safe drinking water or basic sanitation (United Nations 2000). While the UN claimed to have meet the water target, others have shown that the indicators used fail to capture key aspects of the goal, including sustainability, accessibility and safety (Clasen 2012); at the end of 2015, more than 1.3 billion people were estimated to lack safe water (Bain et al. 2013). Among all the MDGs, the least progress was made on the sanitation target. Increases in population largely offset gains in latrine construction, leaving an

estimated 2.3 billion without improved sanitation at the end of the MDG period (WHO and UNICEF 2017).

In 2015, the UN followed the MDGs with the Sustainable Developmental Goals (SDGs) (United Nations 2015). As discussed more fully to follow, SDG Goal 6 seeks to achieve availability and sustainable management of water and sanitation for all by 2030. Achieving the goal would not only advance environmental security, but also make contributions to reducing poverty (Goal 1), ensuring good health and well-being (Goal 3), ensuring quality education (Goal 4), and promoting gender equality (Goal 5). According to the UN, achievement of the SDGs will help advance the overall goal of the ending poverty, protecting the planet, and ensuring prosperity for all (United Nations 2015).

Traditionally, much of the work in water and sanitation has been undertaken by engineers and has consisted of infrastructural improvements. Low-cost community- and household-based interventions, such as protected wells, boreholes, and communal standpipes for improved water supplies, and various types of latrines, septic tanks, and composting systems for improved sanitation, have been largely conceived by and constructed with the assistance of engineers. There are numerous books, manuals, and other resources that describe these systems in detail, including Cairncross and Feachem (1993), the UK Department of International Development (1998), Davis and Lambert (2002), the quarterly *Waterlines*, and the World Bank Water and Sanitation Programme (WSP) 'Field Notes'. Readers are encouraged to refer to such sources for details on the design, installation, and operation of such systems, technology innovations, and the programmatic challenges associated with achieving widespread use on a sustained basis.

This chapter focuses solely on the public health issues concerning water and sanitation. After introducing some basic terminology, it begins by describing the diseases associated with inadequate water and sanitation and their contribution to the overall burden of disease. It then presents evidence of the effectiveness of water and sanitation interventions to prevent such diseases, the economic implications (especially cost-effectiveness and cost–benefits) of such interventions, and some of the other non-health benefits associated therewith. Recent and emerging developments in water, sanitation, and health are then discussed, along with some issues relevant to water and sanitation interventions. The chapter closes with a discussion of some of the continuing challenges in water and sanitation.

Terminology

At the outset, it is useful to understand some of the terminology used in describing the diseases, transmission routes, and interventions associated with the water and

sanitation sectors. Water-related diseases are sometimes classified according to their disease transmission routes as *waterborne* (ingested in drinking water), *water-washed* (associated with inadequate supplies of water for proper personal hygiene), *water-based* (transmitted through an aquatic invertebrate host), or linked to a *water-related vector* (involving an insect vector breeding in or near water) (White et al. 1972). Most waterborne organisms that are human pathogens colonize the gut of humans and certain other mammals and are transmitted through the *faecal–oral* route. The transmission of common waterborne diseases can thus be interrupted by improvements in sanitation (*excreta disposal*), personal hygiene (especially *hand washing with soap*), and microbiological *water quality*, while those that are water-washed are impacted by improvements in *water supplies* (quantity and access) for personal hygiene. Improving water supplies can also help prevent water-based diseases (such as schistosomiasis and dracunculiasis) by reducing the need to enter infected water bodies.

The term ‘sanitation’ is vague and has multiple meanings. Within the public health sector two definitions are used. Under the broader definition, sanitation extends to the process whereby people demand, effect, and sustain a hygienic and healthy environment for themselves. This definition could include safe food production, solid waste management, industrial waste, animal waste, control of chemicals, environmental pollution, storm water drainage, wastewater disposal, human settlements, personal and domestic hygiene, vector and vermin control, occupational health and safety, mining and quarrying, port health, and disposal of the dead. A second definition is more specific, extending only to the process of separating humans from their excreta. This chapter uses this second, more specific definition and regards sanitation as a system in which excreta is: (1) collected safely and with dignity, (2) transported to a suitable location, (3) treated or contained to eliminate pathogenicity, and (4) reused and/or discharged to the environment.

While the MDG targets for water and sanitation were expressed in terms of *sustainable access to safe drinking water* and of *basic sanitation*, the SDGs focus on ‘*safely managed*’ water and sanitation. The WHO/UNICEF Joint Monitoring Programme for Water, Sanitation and Hygiene (JMP) is charged with monitoring progress toward international targets, including the SDGs (WHO/UNICEF 2017). It defines a safely managed drinking water service is one that meets three criteria: it should be accessible on premises, the water should be available when needed, and the water supplied should be free from contamination.

The JMP uses service ladders to benchmark and compare progress across countries (WHO/UNICEF 2017) (Fig. 2.7.1). The bottom rung of the water service ladder is ‘surface water’— drinking water directly from a river, dam, lake, pond, stream, canal, or irrigation canal. The next two rungs are ‘unimproved water

sources’ (surface water and unprotected well/spring) and ‘improved water sources’ (piped-in tap water, borehole/tubewell, protected well/spring, and packaged/delivered water). Under the SDGs, the water service ladder includes three types of improved water services, safely managed, basic, and limited. A ‘safely managed drinking water service’ is one that meets three criteria: it is accessible on premises, the water is available when needed, and the water supplied is free from contamination. If the improved source does not meet any one of these criteria, but a round trip to collect water takes 30 minutes or less, it will be classified as a ‘basic’. If water collection from an improved source exceeds 30 minutes, it is categorized as a ‘limited service’.

The JMP sanitation ladder also has multiple runs. At bottom is ‘open defecation’— disposal of human faeces in fields, forests, bushes, open bodies of water, beaches, or other open spaces, or with solid waste. Moving up the ladder is ‘unimproved sanitation’ (pit latrines without a slab or platform, hanging latrines or bucket latrines), and ‘improved sanitation’ (flush/pour flush to piped sewer systems, septic tanks, or pit latrines, ventilated improved pit (VIP) latrines, and composting toilets, or pit latrines with slabs). Similarly, improved sanitation sources are now subdivided into three groups during the SDG period (safely managed, basic, and limited). For the service level to be ‘safely managed’, the sanitation facilities must be improved and not shared with other households, and the faecal sludge must be (i) treated and disposed of in situ, (ii) stored temporarily and then emptied, transported and treated off-site, or (iii) transported through a sewer with wastewater and then treated off-site. Sanitation services where the faecal sludge is not so managed but where the facilities are otherwise improved facilities that are shared with other households are defined as ‘limited’ and those that are share are defined as ‘limited’ (WHO and UNICEF 2017).

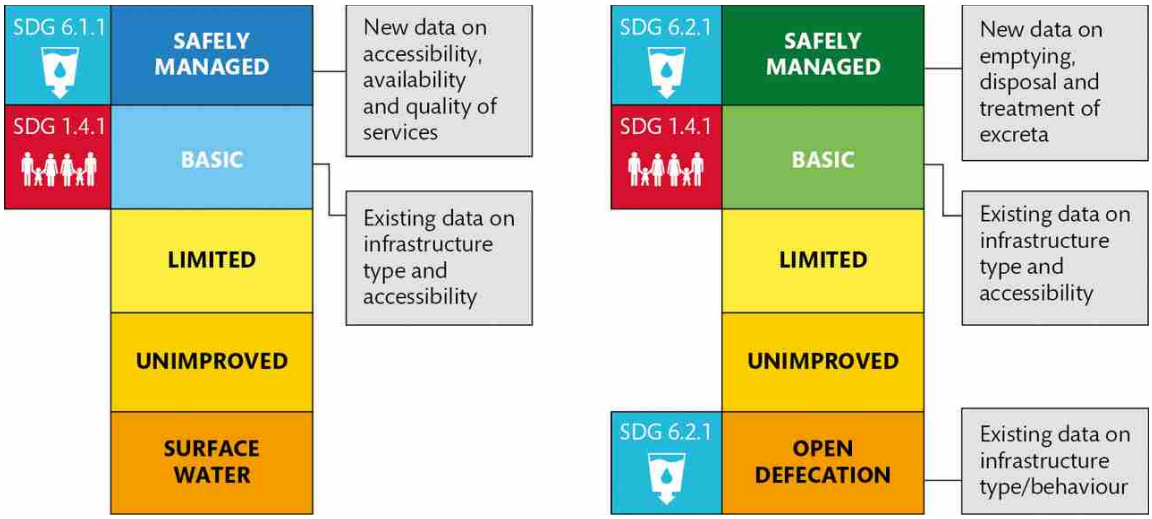

Fig. 2.7.1 Updated JMP service ladders.

Burden of disease

General

Poor water and sanitation are associated with a variety of infectious diseases transmitted through various pathways by helminths, protozoa, bacteria, and viruses. Table 2.7.1 summarizes the most important of these diseases, their transmission routes, aetiological agents, and epidemiological significance. Some of these diseases also contribute to malnutrition, a separate cause of substantial morbidity and mortality that is not reflected in the direct burden of disease figures cited in this chapter (Black et al. 2003).

Certain diseases associated with water are not addressed in this chapter. First, in addition to microbial agents, water is a medium for the transmission of chemical pathogens, including arsenic and other metals, fluoride, nitrates, and volatile organic compounds (including pesticides and herbicides). Accordingly, WHO guidelines and many national water standards establish maximum allowable limits for such chemicals (WHO 2012). However, except for arsenicosis and fluoridosis, which are especially serious in focal areas in Asia and parts of Africa, most of these contaminants represent hazards to health only over the longer term. Second, although improvements in water supplies (to discourage contact with water) and point-of-use water treatment (with filters) are important interventions in preventing dracunculiasis (Cairncross et al. 2002), efforts to control Guinea worm infection have been largely successful and the disease is now of public health interest in

limited areas. Finally, this chapter does not address a variety of diseases associated with waterborne pathogens, such as poliomyelitis and hepatitis A and E, which are controlled mainly by vaccines and other non-environmental measures (Leclerc et al. 2002).

Table 2.7.1 Principal infectious diseases, disease agents, transmission routes, and annual morbidity and mortality related to poor water and sanitation

Disease	Aetiological agent	Transmission	Infected[1] (millions)	Mortality[1] (thousands)
Diarrhoea (dysentery, cholera)	**Virus** *Rotavirus*	Faecal–oral	2,390 (annual morbidity)	1,233–1,391
	Bacteria *Escherichia coli (ETEC)* *Shigella* spp. *Salmonella* spp. *Vibrio* spp. *Campylobacter* sp.	Faecal–oral		
	Protozoa *Giardia lambia* *Cryptosporidium parvum* *Entamoeba histolytica*	Faecal–oral		
Schistosomiasis	*Schistosoma haematobium* *S. mansoni* *S. japonicum*	Penetration through skin exposed to contaminated freshwater	207	4.4
Ascariasis	*Ascaris lumbricoides*	Faecal–oral	807–1.200	2.7
Trichuriasis	*Trichuris trichuria*	Faecal–oral	440	3–10
Hookworm infection	*Necator americanus* *Ancylostoma duodenale*	Penetration through skin exposed to faecally contaminated soil Faecal–oral	460	3–65
Typhoid and paratyphoid fever	*Salmonella* spp.	Faecal–oral	21	177.2
Trachoma	*Chlamydia trachomatis*	Fingers Clothing Eye-seeking flies (*Musca sorbens*) Coughing/sneezing	Blind from trachoma: 1.2 Active trachoma: 21 Trichuriasis: 7.3

Diarrhoeal diseases

Diarrhoeal diseases represent the leading cause of mortality and morbidity associated with unsafe drinking water and poor sanitation. For those infected with the human immunodeficiency virus (HIV) or who have developed acquired immune deficiency syndrome (AIDS), diarrhoea can be prolonged, severe, and life-threatening (Hayes et al. 2003). Diarrhoea is characterized by stools of decreased consistency and increased number. The clinical symptoms and course of the disease vary greatly with the age, nutritional and immune status, and the pathogen (Black and Lanata 1995). Most cases resolve within a week, though a small percentage continue for 2 weeks or more and are characterized as ‘persistent’ diarrhoea. Dysentery is a diarrhoeal disease defined by the presence of blood in the liquid stools. Though epidemic diarrhoea such as cholera and shigellosis (bacillary dysentery) are well-known risks, particularly in emergency settings, their global health significance is small compared to endemic diarrhoea (Hunter 1997). The immediate threat from diarrhoea is dehydration, a loss of fluids and electrolytes. Thus, the widespread promotion of oral rehydration therapy (ORT) has significantly reduced the case-fatality rate associated with the disease. Such improvements in case management, however, have not reduced morbidity, which is estimated at 2.4 billion cases annually (Troeger et al. 2017). And since diarrhoeal diseases inhibit normal ingestion of foods and adsorption of nutrients, continued high morbidity is an important cause of malnutrition, leading to impaired physical growth and cognitive function, reduced resistance to infection, and potentially long-term gastrointestinal disorders.

The infectious agents associated with diarrhoeal disease are transmitted chiefly through the faecal–oral route (Leclerc et al. 2002). Safe excreta disposal thus represents a primary barrier that should contribute to the prevention of indirect transmission via food, water, hands, fomites, and mechanical vectors (flies) (Fig. 2.7.2). A wide variety of bacterial, viral, and protozoan pathogens excreted in the faeces of humans and animals are known to cause diarrhoea. While the importance of individual pathogens varies among settings, seasons, and conditions, a recent

multicountry study has shed important light on the principal aetiological agents responsible for much of the disease burden in Africa and South Asia (Kotloff et al. 2013). Investigators found that most attributable cases of moderate-to-severe diarrhoea were due to four pathogens: rotavirus, *Cryptosporidium*, enterotoxigenic *Escherichia coli* producing heat-stable toxin (ST-ETEC) and *Shigella*. *Aeromonas*, *Vibrio cholerae* O1, and *Campylobacter jejuni* were also important in selected sites. They reported that the odds of dying during follow-up were 8.5 times higher in patients with moderate-to-severe diarrhoea than in controls (odds ratio (OR) 8.5; 95% confidence interval (CI) 5.8–12.5, $p < 0.0001$) and that 88% of deaths occurred during the first 2 years of life. Pathogens associated with increased risk of case death were ST-ETEC (hazard ratio (HR) 1.9; 95% CI: 0.99–3.5) and typical enteropathogenic *E. coli* (HR 2.6; 95% CI: 1.6–4.1) in infants aged 0–11 months, and *Cryptosporidium* (HR 2.3; 95% CI: 1.3–4.3) in toddlers aged 12–23 months. Although diarrhoea is also associated with the ingestion of metals, nitrates, organics, and other chemicals, the burden of disease arising from such exposure is small relative to infectious diarrhoea (Hunter 1997).

Schistosomiasis

Schistosomiasis affects 200 million people all over the world, with *Schistosoma haematobium* and *S. mansoni* being the most common species. The schistosomiasis life cycle involves contamination of freshwater by eggs carrying excreta and urine and an intermediate host, a freshwater snail. Larvae released in the water infect humans by penetrating through the skin. Parasites develop and migrate to the intestines and bladder where thousands of eggs are produced. Like other intestinal helminths, schistosomes are associated with impaired physical and mental development and anaemia. Furthermore, schistosomiasis may cause serious damage to the bladder and intestine walls as a result of parasite egg entrapment within tissues. Chronic infection with *S. haematobium* has been associated with increased risk of bladder cancer in adulthood (Gryssels et al. 2006).

Soil-transmitted helminth infection

Almost 2 billion of the world's population are infected with soil-transmitted helminths. A disproportionate burden of helminthiasis occurs in marginalized, low-income, and resource-constrained regions of the world, largely in developing areas of sub-Saharan Africa, Asia, and the Americas (WHO 2017). About 300 million people suffer from heavy worm load and related severe morbidity (deSilva et al. 2003). *Ascaris lumbricoides*, *Trichuris trichuria*, and hookworm (*Ancylostoma duodenale* and *Necator americanus*) are the most prevalent intestinal helminths. Transmission occurs via ingestion of eggs present in faecally contaminated soil, or via penetration of the larvae through the skin. Children are particularly vulnerable to chronic and heavy infections, which result in malnutrition, stunted growth, reduced physical fitness, and impaired cognitive development (Stephenson et al. 2000). Hookworm infection is an important cause of anaemia, not only in children, but also among women of reproductive age and pregnant women leading to premature birth and low birth weight (Hotez et al. 2004).

Typhoid and paratyphoid fevers

While enteric fevers such as typhoid and paratyphoid were leading causes of waterborne disease in previous centuries, morbidity and mortality diminished dramatically with the provisions of disinfected water supplies and improved sanitary facilities (Cutler and Miller 2005). The aetiological agents for typhoid and paratyphoid fevers are *Salmonella enterica* serovar Typhi (formerly *S. typhi*) and *S. enterica* serovar Paratyphi A and B (formerly *S. paratyphi*). There are an estimated 21 million cases of typhoid annually, causing 148,800 deaths. The milder paratyphoid accounts for an additional 5 million cases each year (Crump et al. 2004; Troeger et al. 2017).

Trachoma

Trachoma accounts for 1.4 per cent of world blindness, with 1.9 million people affected and 190.2 million people living in trachoma endemic areas that are at risk of trachoma blindness (WHO 2017). Trachoma is caused by repeated eye infection with *Chlamydia trachomatis*. Children are the main reservoir for infection, with high prevalence of active trachoma (Mabey et al. 2003). Repeated infections result in deformation of the upper eye lid, abrasion of the cornea, and progressive loss of vision in later life. *C. trachomatis* is transmitted from the discharge of an infected eye via contaminated fingers, clothing, and eye-seeking flies (*Musca sorbens*) (Hu et al. 2010). Although the role of flies in the transmission of infection remains unclear, studies have shown that *M. sorbens* breed mainly in solid human faeces present in the environment and not in latrines (Emerson et al. 2000). Thus, safe excreta disposal may play an important role in reducing trachoma transmission. Improving water supplies and sanitation is part of the WHO-backed SAFE (surgery, antibiotics, facial hygiene, environmental improvement) strategy for controlling and preventing the disease.

Malnutrition

Water and sanitation are also linked to malnutrition, a separate source of significant morbidity and mortality. An estimated 165 million children under 5 are stunted (i.e. have a height-for-age Z score of less than −2); 55 million children are wasted (i.e. have a weight-for-height Z score of less than −2), of whom 19 million have severe wasting (weight-for-height Z score of less than −3) or severe acute malnutrition (weight-for-height Z score of –3 or lower or associated oedema) (Bhutta et al. 2013). Child underweight or stunting causes about 20% of all mortality of children younger than 5 years of age; it also contributes to long-term cognitive impairment, poorer performance in school, fewer years of completed schooling, and lower adult economic productivity.

Effectiveness of water and sanitation in preventing disease

Barriers to transmission of faecal–oral diseases

As illustrated by the so-called ‘F-diagram’ (Fig. 2.7.2), the safe disposal of human faeces is the primary barrier in preventing faecal–oral transmitted diseases. Without removing excreta from potential contact with humans, animals, and insects, pathogens may be carried on unwashed hands, in contaminated water or food, or via flies and other insects on to further human hosts. Whether or not

sanitation is adequate, hands can become contaminated with faeces, especially during anal cleansing following defecation or in cleaning a child after defecation. This may result in further transmission, either directly or indirectly through food, water, or other beverages, or fomites. Accordingly, hand washing is an important secondary barrier to faecal–oral disease transmission (Curtis and Cairncross 2003). Other secondary barriers include: (1) water quality interventions (e.g. safe distribution and storage or use of boiling or other point-of-use water treatment); (2) water supply interventions to increase the quantity and availability of water for personal and domestic hygiene; (3) proper cooking and food handling; and (4) control of mechanical vectors such as flies.

Evidence of effectiveness

Scores of studies have been conducted and published on the effectiveness of water, sanitation, and hygiene interventions to prevent infection and disease. Systematic reviews (Chapter 5.15) are a means of identifying, summarizing, synthesizing, explaining, and assessing the methodological quality of evidence of the effectiveness of health interventions with a variety of studies relating to a particular health intervention. In some cases, such reviews also employ meta-analyses or other statistical methods to estimate the pooled effect of the intervention across the studies included in the review. A number of such reviews have examined the evidence of effectiveness of water, sanitation, and hygiene interventions to prevent disease and infection.

Diarrhoeal diseases

Table 2.7.2 summarizes the results of seven different systematic reviews of water and sanitation interventions to prevent diarrhoeal diseases published over the last 25 years. While there is conflicting evidence on the impact of water supply (quantity and access), there is consistent evidence that improvements in water and sanitation can make substantial contributions to the prevention of diarrhoeal diseases.

Soil-transmitted helminth infection

One review assessed not only the impact of sanitation interventions on soil-transmitted helminth infections, but also water and hygiene (Strunz et al. 2014). The review covers 94 studies, though only 5 were randomized controlled trials. Use of treated water was associated with lower odds of infection from any soil-transmitted helminth (OR 0.46, 95% CI 0.36–0.60). Piped water access was

associated with lower odds of *A. lumbricoides* (OR 0.40, 95% CI 0.39–0.41) and *T. trichiura* infection (OR 0.57, 95% CI 0.45–0.72), but not any soil-transmitted helminth (STH) infection (OR 0.93, 95% CI 0.28–3.11).

Comparatively, the most recent review by Freeman et al. (2017) examined 65 studies, including 31 from the 2014 Strunz review. The overall effect of sanitation was associated with lower odds of infection for *A. lumbricoides* (OR 0.73, 95% CI 0.61–0.86) and Hookworm (OR 0.65, 95% CI 0.53–0.78), but not *T. trichiura* (OR 0.80, 95% CI 0.63–1.03).

When examining the association between STH infections and any sanitation vs. none/non-use, a protective association was found for all STH infections with pooled ORs of 0.63 (95% CI: 0.49–0.81), 0.72 (95% CI: 0.55–0.95), and 0.61 (95% CI: 0.51–0.72), for *A. lumbricoides*, *T. trichiura*, and hookworm respectively. However, when restricted to intervention studies alone, no association was found between STH infections and sanitation: *A. lumbricoides* (OR 0.77, 95% CI: 0.49–1.21), *T. trichiura* (OR 1.00, 95% CI 0.37–2.69), and hookworm (OR 0.94, 95% CI 0.76–1.15). The researchers attribute this result to the low number of such studies available (Freeman et al. 2017).

Table 2.7.2 Estimate of effect[1], [2] (and number of studies in square brackets) of systematic reviews of water and sanitation interventions to prevent diarrhoeal diseases

Intervention (Improvement)	Esrey et al. (1985) (range)	Esrey et al. (1991)	Fewtrell et al. (2005) (95% CI) (No. studies)	Clasen et al. (2006) (95% CI) (No. studies)	Waddington et al. (2009) (95% CI) (No. studies)	Wolf et al. (2014) (95% CI)[2]	Clasen et al. (2015) (95% CI) (No. studies)	Freeman et al. (2017) (95% CI) (No. studies)
Water quantity	25% (0–100%) [17]	27% [7]						
Water quality			0.69 (0.53–0.89) [15]	0.57 (0.46–0.70) [38]	0.58 (0.50–0.67) [31]		0.59 (0.51–0.69)	
Source	16% (0–90%) [9]	17% [7]	0.89 (0.42–1.90) [3]	0.73 (0.53–1.01) [6]	0.79 (0.62–1.02) [3]	0.89 (0.78–1.01)	0.76 (0.48–1.19) [6]	
Household (point of use)			0.65 (0.48–0.88) [12]	0.53 (0.39–0.73) [32]	0.56 (0.45–0.65) [28]		0.58 (0.48–0.69) [58]	
Chlorination				0.63 (0.52–0.75) [16]		0.63 (0.55–0.72)	0.72 (0.61–0.84) [19]	
Filtration				0.37 (0.28–0.49) [6]		0.41 (0.33–0.50)	0.48 (0.38–0.59) [23]	
Solar disinfection				0.69 (0.63–0.74) [2]		0.63 (0.55–0.72)	0.62 (0.42–0.94) [4]	
Floc-disinfection				0.69 (0.58–0.82) [6]			0.48 (0.20–1.16) [7]	

Intervention (Improvement)	Esrey et al. (1985) (range)	Esrey et al. (1991)	Fewtrell et al. (2005) (95% CI) (No. studies)	Clasen et al. (2006) (95% CI) (No. studies)	Waddington et al. (2009) (95% CI) (No. studies)	Wolf et al. (2014) (95% CI)[2]	Clasen et al. (2015) (95% CI) (No. studies)	Freeman et al. (2017) (95% CI) (No. studies)
Water supply (point-of-distribution)	37% (0–82%) [8]	16% [22]	0.75 (0.62–0.91) [6]	0.73 (0.53–1.01) [6]	0.98 (0.89–1.06) [8]	0.89 (0.78–1.01)		
Water supply and sanitation/hygiene		20% [7]			0.43 (0.33–0.55) [3]			
Sanitation	22% (0–48%) [10]	22% [11]	0.68 (0.53–0.87) [2]		0.63 (0.43–0.93) [6]	0.84 (0.77–0.91)		0.88 (0.83–0.92) [27]

Note:

[1] for studies by Esrey and colleagues, estimate of effect is the median reduction in diarrhoeal disease from the reported studies; for other studies, estimate of effect is the pooled risk ratio from meta-analysis using random effects model. To compare results, the percentage reduction is 1 −RR (e.g. RR of 0.69 implies a 31% reduction in risk).

[2] Pooled estimates of effect in settings with unimproved water supply and prior to adjustment for non-blinding. For household interventions, estimates are for studies that combine treatment with safe storage.

Schistosomiasis

Esrey and colleagues (1991) reported a median reduction in the prevalence of schistosomiasis of 73% (range 59–87%) from four water and sanitation interventions; the reduction was 77% among the three studies they deemed rigorous. Piped-in water supplies and community washing and bathing facilities that reduced contact with surface waters were especially protective, leading to reductions in both prevalence and severity (Esrey et al. 1991). The reviewers noted that in Kenya, the installation of boreholes without laundry or shower facilities failed to reduce infection.

Two quasi-randomized, controlled interventional studies from China also suggest that improved excreta disposal is protective against schistosomiasis. In a 3-year quasi-randomized controlled trial (RCT), Chen et al. (2004) recorded a 43% reduction from combined water, sanitation, and hygiene interventions that also included a snail control component. Zhang et al. (2005) reported a 45% reduction in a 2-year quasi-RCT that included water, sanitation, and hygiene. Once again, these trials did not include sufficient clusters to reliably calculate confidence intervals around the point estimates of effect.

Typhoid and paratyphoid

No RCTs of water or sanitation interventions to prevent typhoid or paratyphoid have been reported. A recent review of global trends in these enteric fevers identified little direct evidence of the potential contribution of water or sanitation interventions (Crump and Mintz 2010). Nevertheless, there is evidence suggesting the effectiveness of water quality interventions. Cutler and Miller (2005) have shown the historical evidence on reductions in mortality associated with the introduction of clean water and sanitation in the United States. Case–control studies do suggest that the diseases are still associated with unsafe water and sanitation. In a study in Uzbekistan where typhoid remains endemic, cases were more likely to drink unboiled surface water outside the home (OR 3.0; 95% CI: 1.1–8.20) (Srikantiah et al. 2007). In a similar case–control study in Bangladesh, drinking unboiled water at home was a significant risk factor (OR 12.1; 95% CI: 2.2–65.6) (Ram et al. 2007). Among the risk factors for typhoid and paratyphoid in an urban setting in Indonesia were lack of a toilet in the household (OR 2.20; 95% CI: 1.06–4.55) and use of ice cubes (OR 2.27; 95% CI: 1.31–3.93). Enteric fevers are also a risk among travellers to endemic area, but effective vaccines are usually recommended against the risk of waterborne or food-borne transmission.

Trachoma

The evidence of the effectiveness of environmental interventions (including water and sanitation) alone to prevent active trachoma is not clear (Rabiu et al. 2012). Reviews of the WHO-backed SAFE strategy for trachoma control conclude that there is comparatively weak evidence of the effectiveness of the ‘F’ (facial cleanliness) and ‘E’ (environmental improvement) components that encompass improved access to water and better sanitation (Emerson et al. 2000a; Kuper et al. 2003). In a 6-month cluster RCT of 21 villages in the Gambia, Emerson and colleagues (Emerson et al. 2004) reported a reduction in fly catches among study clusters receiving latrines. However, the prevalence of active trachoma associated with the intervention was not statistically lower than among seven control clusters (relative risk (RR) 0.81; 95% CI: 0.54–1.22). The study has not been repeated. In another review, overall sanitation was associated with lower trachoma as measured by the presence of trachomatous inflammation-follicular or trachomatous inflammation-intense (TF/TI) (OR 0.70, 95% CI 0.62–0.79) and *C. trachomatis* infection (OR 0.62, 95% CI 0.44–0.87) (Freeman et al. 2017). Altogether, findings from this study provide strong evidence for the association between sanitation and active trachoma in both observational and intervention studies; however, the impact upon *C. trachomatis* is less conclusive due to lack of intervention studies conducted.

Malnutrition

Malnutrition is linked to water and sanitation, both through food production (irrigation and safe use of waste for fertilizer) and by preventing diarrhoea and enteric infections that interfere with normal adsorption of nutrients (Fewtrell et al. 2007). An association of malnutrition with diarrhoea has been well established, but the impact of interventions is less clear. In a pooled analysis of nine studies with diarrhoea and growth data for 1,393 children, the probability of stunting at 24 months of age increased by 2.5 per cent per episode of diarrhoea, and 25% of all stunting in 24-month-old children was attributable to having five or more episodes of diarrhoea in the first 2 years of life (Checkley et al. 2008). The Maternal and Child Undernutrition Series in *The Lancet* estimated that sanitation and hygiene interventions implemented with 99% coverage would reduce diarrhoea incidence by 30%, which would in turn decrease the prevalence of stunting by only 2.4 per cent (Bhutta et al. 2013). A report for the World Bank suggests that open defecation explained 54% of international variation in child height by contrast with gross domestic product, which only explained 29% (Spears 2013). However, a recent systematic review and meta-analysis of sanitation's effect on infectious disease and nutritional status found no evidence of impact on weight-for-age Z-scores, weight-for-height Z-scores, and only a borderline effect on height-for-age Z-scores in children under 5 years of age (Freeman et al. 2017).

Other benefits of water and sanitation interventions

Improving water availability (quantity and access)

As the section 'Evidence of effectiveness' suggests, improving water availability—even without a corresponding improvement in water quality—is associated with reductions of diseases transmitted through waterborne, water-washed, and water-based routes. This is partly due to the well-established relationship between the amount of water that people use and the time required to collect it (Cairncross and Feachem 1993). Figure 2.7.2 shows the L-shaped curve that characterizes water consumption patterns based on service levels. While significant quantities of water are used if delivered directly to the home, the quantity used is fairly constant when the collection time is 5–30 minutes and further diminishes for longer collection times. In lower-income settings, average daily per capita consumption is about 150 L for those with household connections, 50 L for yard taps, and just 15 L for communal sources such as stand posts, wells, and springs. Thus, assessments of water availability are expressed in terms of distance: normally 1 km or round trip

collection time (normally 30 minutes) (WHO and UNICEF 2013) but 0.5 km in disaster response (Sphere Project 2004).

A WHO report concluded that a minimum quantity of water for basic health protection is 20 L/person/day (Hutton and Bartram 2003). Of this, 7.5 L is for consumption (hydration and food preparation) and therefore must be of a quality to present minimal health risk; the balance is for basic personal and domestic hygiene. The report recognizes, however, that in addition to the direct health benefits associated with improving water supplies, there are indirect health and other benefits. Indirect health benefits may accrue from reducing the amount of time collecting water which can then be used more effectively at home caring for children or engaging in other productive activities (Cairncross 1987). Services at clinics, medical posts, and other healthcare facilities also benefit from improved water supplies. Sufficient water for irrigating gardens and crops can improve nutrition and generate income (Thompson et al. 2001). Vending water and making and selling beverages can also impact poverty. Finally, to the extent that people are paying for water, improved water supplies may result in savings that can be used for food and other necessities that may impact health outcomes.

Improved school attendance

Although weaker than often asserted, there is some evidence that water and sanitation interventions at schools can improve school attendance (Sclar et al. 2017). A recent study from India showed that a national government programme to install toilets in schools resulted in an 8% increase in enrolment among pubescent-age boys and girls and a 12% increase among younger children of both genders (Adukia 2014). In Africa alone, Hutton et al. (2007) estimated that meeting the MDGs for water and sanitation would increase school attendance by 99 million days annually; full access to basic water and sanitation for all would increase school attendance by 140 million days each year. The sanitary needs of girls and the negative impact of lack of sanitation adversely impacts their attendance levels. In a recent trial in Kenya, schools with poor water access during the dry season that received combined water supply, hygiene promotion and water treatment together with improvements in sanitation experienced an increase in average attendance equal to 26 additional pupils per school on average (Garn et al. 2013). The proportion of girls enrolled in school also increased by 4%. In Uganda, 94% of girls reported problems at school during menstruation and 61% reported staying away from school (IRC International Water and Sanitation Centre 2006). Cultural and religious constraints in many settings make menstruation a taboo. If menstruation lasts over a week, there is a tendency for girls to skip the entire school year (Bharadwaj and Patkar 2004). Sanitation can play an important role in

improving educational access for children with disabilities, through the improvement of paths, latrine floors, and installation of handrails (Bannister et al. 2005).

Security and gender equality

Improved sanitation and water supplies advance security and gender equality for women and girls (Caruso et al. 2017a). Household sanitation can increase their safety by avoiding the dangers of sexual assault and harassment faced when practising open defecation or using latrines away from their homes. Safe, private, and proximate latrines are now considered a basic human right (United Nations 2010); they are a particular issue for women in emergencies and conflicts (Sphere Project 2004). Research in Kenya revealed that women would defecate into plastic bags and throw them into streets ('flying toilets') because they feared being raped when using latrines shared with men (Maili Saba Research Report 2005). They were also afraid of being seen to be using latrines too regularly and preferred to bathe within their own homes after dark where they felt safer. Caruso and colleagues have developed a scale for assessing sanitation insecurity among women (2017). In a study in rural India, women reported unaddressed urination, defecation and menstruation concerns due to inadequate sanitation facilities and were linked with an array of adverse adaptations (suppression, withholding food and water) and consequences (scolding, shame, fear) (Caruso et al. 2017b). Young children often prefer open defecation due to fear of falling into pits in poorly-designed or unsuitably-adapted latrines.

HIV/AIDS

It is well known that access to safe drinking water and sanitation prolongs the lives of people living with HIV/AIDS (PLWHA) by reducing the risk of opportunistic infections, including diarrhoeal diseases (Peletz et al. 2013). Household-based water treatment has been shown to be an effective intervention in preventing mortality and morbidity in a population with one or more persons infected with HIV (Colford et al. 2005; Lule et al. 2005; Peletz et al. 2012). A recent systematic review by Yates and colleagues (2015) further confirmed these results, finding that household water treatment, water supply, and hygiene interventions reduced morbidity from diarrhoea and waterborne disease-causing agents in PLWHA. There is also evidence that household-based water filters and insecticide-treated bednets for malaria slow the progression of HIV (Walson et al. 2013). Water and sanitation are now recognized as particular priorities in-home-based care of

PLWHA (WHO 2008). Point-of-use water treatment products are now included in health kits for people living with HIV/AIDS (Colindres et al. 2007).

Recent and emerging developments in water and sanitation

SDGs in water and sanitation

The MDG water and sanitation targets—to halve the proportion of the 1990 population without sustainable access to safe drinking water and basic sanitation—have been a major factor in mobilizing efforts to expand water and sanitation coverage. While there is still some controversy about JMP claims on the water target and overall disappointment on progress to the sanitation target, successor goals have now been established. SDG targets 6.1 and 6.2 relate to drinking water, sanitation, and hygiene. They represent significant advancements the MDG by (i) calling for universal (as opposed to reducing by half those who were unserved) and addressing inequalities in service levels, (ii) addressing hygiene, which was not been included in the MDGs, (iii) specifically requiring that drinking water should be safe and affordable, and that sanitation should be adequate, and (iv) including explicit references to ending open defecation and to the needs of women and girls and those in vulnerable situations. As discussed just now, the JMP has developed enhanced indicators that allow for more direct monitoring of the new water and sanitation targets (WHO and UNICEF 2017).

WHO Guidelines on Sanitation

While the WHO has long established guidance on water (e.g. Guidelines for Drinking Water Quality, GDWQ) and certain aspects of excreta management. For the first time in 2018, the WHO has published a set of Guidelines on Sanitation (WHO 2018)). The guidelines are intended to set forth a comprehensive framework for health-protecting sanitation, covering policy formulation, implementation of sanitation technologies and behavioural interventions, risk-based hazard identification, and management approaches and monitoring. They also aim to provide an authoritative basis for the effective consideration of public health in setting international, regional, national, or municipal sanitation policies and actions. They are intended to encourage achievable practices and the formulation of sound regulations, applicable to low-income, middle-income, and industrialized countries alike. The guidelines provide three general recommendations that emphasize the need for universal coverage and use of sanitation, focus on the entire faecal management chain, and encourage linkages with other sectors. More specific guidance is provided on best practices. Like the

GDWQ, the Guidelines on Sanitation are seen as an evolving document that will reflect emerging research and experience in sanitation.

Systems approach to understanding enteric pathogen transmission

Much of the research described in previous sections regarding the health impact of water and sanitation interventions has focused on assessing the impact of interrupting particular transmission pathways. Increasingly, epidemiologists are recognizing the interaction and interdependencies that characterize the transmission of enteric pathogens. This is leading to calls for a systems approach that not only acknowledges the multiple transmission pathways and varied aetiological agents involved in diarrhoea and other enteric diseases but also their dynamism and the community level impact of interventions (Eisenberg et al. 2012). Examples of this community effect are the health benefits that inure to non-adopters who live adjacent to households with latrines or who practise effective household water treatment. Interventions that interrupt transmission of one or more pathways can also impact transmission through other pathways of one or more pathogens. It is important that studies endeavour to capture externalities and the wider impact of an intervention at the community level, both to understand and design interventions that that optimize this larger effect and to correctly assess the impact (and cost-effectiveness) of the interventions.

Need for consistency/adherence in safe water consumption

Epidemiological modelling using QMRA has also been used to estimate the impact of sporadic exposure to contaminated drinking water, either as a result of interruptions in water supplies (Hunter et al. 2009) or from inconsistent use of point-of-use water treatment (Brown and Clasen 2012; Enger et al. 2013). The models show that in settings with moderately contaminated water supplies, much of the health benefit from improved drinking water quality is vitiated by even occasional consumption of untreated water. These results raise questions about the health benefits that can be gained from unreliable water supplies. Moreover, insofar as point-of-use water treatment campaigns often fail to achieve high levels of adherence, these models raise questions about the potential health benefits from household-based water treatment.

Household-based water treatment

For the hundreds of millions who lack household water connections that provide drinking water on a 24/7 basis, water is often collected and stored in the home until

needed. It is well known that even water that is safe at the point of collection undergoes frequent and extensive re-contamination during collection (or compromised distribution), storage, and use in the home (Wright et al. 2004). While providing safe, piped-in, disinfected water to each household is an important goal, even the purported achievement of the MDG water target leaves more than three-quarters of a billion people without access to improved water and hundreds of millions more without safe drinking water (Clasen 2012). Accordingly, the WHO and others have called for other approaches that will accelerate the heath and economic gains associated with safe water while progress is made in improving infrastructure.

Household water treatment and safe storage (HWTS) represent one such alternative (Sobsey 2002). Boiling, filtering, and chemically disinfecting water in the home are already in use, with more than 1 billion people reportedly treating their water at home before drinking it (Rosa and Clasen 2010). Recent systematic reviews have shown household-based interventions (home-based boiling, chlorination, filtration, solar disinfection, and flocculation/disinfection) to be significantly more effective than traditional, non-reticulated source-based interventions (protected wells and springs, boreholes, communal tap stands) in improving microbiological water quality and reducing diarrhoeal disease (Fewtrell et al. 2005; Clasen et al. 2015).

Shared and public sanitation

An estimated 600 million people—including a fifth of the population of sub-Saharan Africa—rely on public or other shared sanitation facilities (WHO and UNICEF 2017). Historically, such shared facilities were excluded from the definition of ‘improved’ sanitation for purposes of monitoring progress toward the MDG sanitation target, regardless of the level of service or number of people sharing them, because they are deemed unacceptable, unhygienic, and inaccessible. As discussed previously, the JMP made a revision to this policy that allows shared latrines to be considered ‘improved’ and categorized as a ‘limited’ sanitation service if they utilize wet or dry sanitation technologies and are shared by two or more households (WHO and UNICEF 2017). However, there is little evidence to support this change. A systematic review and meta-analysis of 11 studies reporting on diarrhoea found increased odds of disease associated with reliance on shared sanitation (OR 1.39; 95% CI: 1.14–1.70) (Heijnen et al. 2014). While there was some evidence of increased risk with the number of households sharing, there was an elevated risk at any level of sharing. An analysis of JMP data also found evidence of increased risk of diarrhoea associated with sharing latrines, even after adjusting for likely confounders (Fuller et al. 2014).

Safe disposal of child faeces

While there are few published studies, the evidence suggests that in many low-income settings, nappies and potties are rarely available or used, making the hygienic collection of early child faeces difficult; if collected, such faeces are often disposed of in a manner that does not prevent further exposure (Gil et al. 2004). In fact, the unsanitary disposal of child faeces may present a greater health risk than that of adults. First, young children represent the highest incidence of enteric infections, and their faeces are most likely to contain agents. Second, young children tend to defecate in areas where susceptible children could be exposed. Third, young children who are also most at risk of mortality and the serious sequelae associated with enteric infection are most likely to be exposed to these ambient agents due to the time they spend on the ground, their tendency to put fingers and fomites in their mouths, and common behaviours such as geophagia. In a meta-analysis of ten observational studies published between 1987 and 2001, Gil et al. (2004) found that child faeces disposal behaviours considered risky (open defecation, stool disposal in the open, stools not removed from soil, stools seen in household soil, and children seen eating faeces) were significantly associated with an increased risk of diarrhoeal diseases (RR 1.23; 95% CI: 1.15–1.32); behaviours considered safe (use of latrines, nappies, potties, toilets, washing diapers) was borderline protective (RR 0.93; 95% CI: 0.85–1.00).

There is evidence that even households with latrines often fail to disposal of child faeces safely; more commonly, they are either not collected or are disposed of with the household's other solid waste (Majorin 2012; Majorin et al. 2014). By definition, this renders the practice 'open defecation' even though these households are usually counted as having 'improved sanitation' due to the presence of the latrine (WHO and UNICEF 2013). Efforts to end open defecation will not be successful unless they include interventions to ensure the safe disposal of child faeces.

Technological and programmatic innovations

Steps to improve water supplies and sanitation, particularly in rural and remote locations, have proved especially challenging. Despite concerted efforts over past decades, vast numbers in Africa and South/South East Asia still lack improved water and sanitation (WHO and UNICEF 2017). While a variety of communal and household-level options have been promoted as alternatives to customary approaches in order to improve water quality, quantity, and proximity, some of these have been found wanting in terms of technological suitability, cost, and sustainability. New challenges include natural or man-made chemical contamination, saline intrusion, increasing urbanization, falling water tables,

threats associated with climate change, and increasing demand for agricultural and industrial uses of water. High upfront costs, lack of financing, uncertain land tenure, inadequate skilled masons for construction, pit-emptying, longer-term waste disposal, and urbanization are major challenges in sanitation.

Public health professionals, donors, programme implementers, social entrepreneurs, and the private sector have responded to these challenges by developing and promoting a variety of technological and programmatic innovations for improving water supplies and sanitation, especially among low-income populations. In water, these include developments in rainwater harvesting, water locating, borehole drilling, well digging, locally fabricated pumps, and other water lifting devices, self-supply strategies, small community water treatment and/or distribution systems, water filling stations/kiosks, and a variety of point-of-use water treatment technologies. In sanitation, much of the effort in low-income settings focuses on improved on-site solutions in rural settings and alternatives to conventional sewerage in urban settings. Communal private latrines have been promoted widely in India and elsewhere. New technologies include cheaper, lightweight squatting slabs, composting toilets, digestion chemicals, multichamber pits, pit-emptying, and improved separation of liquid and solid excreta. Sludge is increasingly being viewed as a useful product rather than waste, with innovations in collection and processing. Many of these innovations are accompanied by entrepreneurial initiatives and public–private partnerships; others through micro-finance and base-of-the-pyramid marketing. While some of these innovations appear promising, lessons from the past suggest that understanding and responding to the particular circumstances present in a given setting—and especially what the target population itself wants and is willing to pay for—are especially important in achieving large-scale sustainable improvements that will also impact public health. Technical innovations in water and sanitation that do not address the need for behaviour change are also unlikely to achieve optimal uptake and impact.

Community-led total sanitation

First developed in Bangladesh in 1999 and expanding widely elsewhere, community-led total sanitation (CLTS) is an approach that empowers local communities to stop open defecation and to build and use latrines without the support of external hardware subsidies. Through the use of participatory techniques, community members analyse their own sanitation situation, including the extent of open defecation and the possibilities of faecal–oral contamination. This is designed to ignite a personal sense of disgust and shame that translates into collective action to reduce the impact of open defecation (Kar 2003). By triggering collective behaviour change, CLTS places the community, rather than the

household, at the centre of the decision-making process. Peer pressure and civic pride are important motivating factors. The particular design of a latrine is secondary to the emphasis on 100% coverage. The results can be impressive, with whole communities changing from open defecation to latrine use in a matter of months (Kar 2003). The approach has since been rolled out in Africa and Asia, and there is some evidence of its sustainability (Kar and Bongartz 2006).

Nevertheless, a recent systematic review of included 200 studies of CLTS interventions concluded that the evidence base on CLTS effectiveness is weak (Venkataramanan 2018). They found that 14 quantitative evaluations reported decreases in open defecation, but did not corroborate the widespread claims of open defecation-free (ODF) villages found in case studies; they also found that over a quarter of the literature overstated conclusions, attributing outcomes and impacts to interventions without an appropriate study design. The authors highlighted the need for more rigorous research on CLTS impacts as well as applied research initiatives that bring researchers and practitioners together to address implementation challenges to improve rural sanitation efforts.

Sanitation marketing

Sanitation marketing uses a commercial approach to the production and delivery of sanitation technologies and engages the private sector for production and delivery in a financially and institutionally sustainable manner (Jenkins and Sugden 2006). Such a marketing approach has been recommended over typical public sector promotion of sanitation since it helps ensure that people choose to receive what they want and are willing to pay for, is financially sustainable, is cost-effective, and can be taken to scale (Cairncross 2004). Sanitation marketing adopts a consumer perspective, starting with an understanding of which products and services the target population wants, will pay for, will maintain, and are appropriate to the local context. It seeks to develop a sustainable sanitation industry, which is not dependent on external donors for hardware subsidies or long-term support for its continuation (Water and Sanitation Programme n.d.). It recognizes the household as the key decision-maker regarding their defecation practice and the importance of effective public–private partnerships. The extent to which the approach is capable of reaching the base of the economic pyramid has not yet been shown.

Enteropathy

Beyond the impact of diarrhoea on malnutrition, researchers have postulated that repeated exposure to faecal pathogens may be a significant cause of environmental

(tropical) enteropathy, a subclinical condition characterized by malabsorption, villus atrophy, crypt hyperplasia, T-cell infiltration, and general inflammation of the jejunum (Humphrey 2009). Enteropathy is caused by faecal bacteria ingested in large quantities by young children living in conditions of poor sanitation and hygiene. Humphrey has suggested that that the primary causal pathway from poor sanitation and hygiene to undernutrition is tropical enteropathy and not diarrhoea. If so, current estimates may have substantially underestimated the contribution of sanitation and hygiene to growth because the effect is modelled entirely through diarrhoea. A recent study in Bangladesh found that markers of enteropathy linked to unhygienic environments (Lin et al. 2013). However, recent randomized controlled studies have shown mixed results on the efficacy and effectiveness of water and sanitation interventions to prevent stunting (Pickering and Davis 2012; Luby et al 2018, Null et al. 2018). This has raised questions about the link between enteropathy and stunting and the potential of environmental interventions to prevent it.

Challenges in water and sanitation

Failure to treat diarrhoea as a serious disease

One of the threshold constraints to scaling up water and sanitation is the belief that diarrhoea—the main health threat associated with poor water and sanitation coverage—is not a disease. Figueroa and Kincaid (2010) cite numerous studies from various countries in which participants reported diarrhoea to be a natural and even desirable condition, especially in young children, not worthy of special preventive measures. Although health benefits often lack significant motivational impetus for driving preventive measures, the fact that diarrhoea is not even considered a disease by many of the most vulnerable populations further limits this strategy. Among policymakers and health officials faced with a variety of life-threatening diseases, diarrhoea may not receive the commitment of resources that its status as the third leading cause of morbidity and mortality from infectious disease would suggest it deserves.

Lack of public sector coordination

In most countries, a variety of agencies and authorities are responsible for some part of water and sanitation. These typically include the ministries of water, health, water resources, environment, local government, rural development, and education. In many cases, there are also federal, regional, district, and local levels of government. Rarely do any of these ministries take full responsibility for all

aspects of water or of sanitation. The result is often a patchwork effort that lacks funding and coordination. There are important examples of successful coordinated public sector efforts. In South Africa, strides in sanitation are occurring because of a national decision and plan which set out targets, clear strategies, significant resources, and accountability (Muller 2002). Ethiopia has also achieved considerable success in improving water and sanitation coverage, particularly in the Southern Nations, Nationalities and Peoples Region, where a commitment at the senior levels translated into coordinated and sustained action (Bibby and Knapp 2007).

Mixed results from water and sanitation interventions

The research just described provides consistent evidence of an association between poor water and sanitation conditions and adverse health outcomes. Nevertheless, a series of recent efficacy studies of WASH interventions have raised questions about the potential of existing approaches to achieve the health outcomes have been shown in systematic reviews (Luby et al. 2018; Null et al. 2018, SHINE trial). Continued research is necessary in order to provide more guidance on the means of optimizing scalable water and sanitation interventions in low-income settings.

Conclusion

Unlike many of the other challenges in public health, the solutions for eliminating most of the disease burden associated with poor water and sanitation are well known. All but the poor have enjoyed the health, economic, and other benefits associated with safe drinking water and basic sanitation for decades. The fact that hundreds of millions still lack access to these fundamental resources is a scandal that generations have allowed to persist simply as a matter of misguided priorities. And as the ‘haves’ continue to make rapid gains, they are not only increasing the gap over the ‘have-nots’ but also using up larger amounts of the world’s limited water supplies and capacity for waste disposal, making it more difficult and costly for others to join their privileged club.

The need to extend water and sanitation coverage is acknowledged at the highest international levels, and progress is being made. Whether these efforts will be any more successful than those expressed in previous international declarations and goals is not yet clear. As the poor continue to wait for the piped-in water supplies and sanitary disposal that they deserve, however, it is incumbent on the public health community to develop, assess, and promote effective, low-cost, and sustainable alternatives and creative delivery strategies in order to accelerate access to the health gains associated with safe drinking water and basic sanitation.

Key points

While safe drinking water and sanitation are widely recognized as fundamental public health interventions, eight per cent of the world's population still lack improved water supplies and 30% lack basic sanitation.

The infectious diseases associated with unsafe drinking water and poor sanitation impose a heavy burden, especially on the poor, the very young, and the immunocompromised; they also aggravate poverty, education, and economic development.

There is strong evidence that interventions to improve water supplies or sanitation can be effective in preventing diarrhoea, soil-transmitted helminth infections, schistosomiasis, and typhoid fevers.

Water and sanitation interventions have also been shown to be cost-effective and cost-beneficial, with significant savings to the public sector from reduced healthcare costs; there is also evidence of other economic and developmental benefits from improved access to water and sanitation.

A variety of recent and emerging developments, including new methods for assessing and monitoring the risk of diseases associated with water and sanitation as well as alternative technologies, programmatic approaches, and implementation strategies, may contribute to improved targeting, coverage, uptake, and sustainability.

Nevertheless, significant political, social, economic, and developmental challenges must be addressed in order to successfully scale up some of these interventions on a sustainable basis and thus provide the most vulnerable populations with the health and other benefits of safe drinking water and sanitation.

Food and nutrition

Roger Shrimpton, David Sanders, and Anne Marie Thow

Introduction

Nutritional science concerns the study of nutrients in food, how the body uses nutrients, and the relationship between diet, health, and disease. In previous centuries the focus was more on identifying the nutrient components in the diet, and single nutrient deficiencies, such a scurvy caused by vitamin c deficiency, beriberi caused by thiamine deficiency, and goitre caused by iodine deficiency. By the end of the Second World War, virtually all the nutrients had been identified and the work was thought to have been completed (Carpenter 2003). Early nutrition programme efforts around the turn of the millennium focused on tackling child undernutrition especially, but in more recent times nutrition science has begun to study population-based evidence for the relationships between specific dietary patterns, nutrient intakes, and the non-communicable diseases of obesity, cancer, diabetes, and atherosclerosis.

Nutrition paradigms have shifted in the last few decades, and now there is an urgent need for the policy discourse and public health practice to catch up. Effective public health policy and practice responses to nutrition depend on an accurate understanding of the problem of ‘malnutrition’, its implications for human health, and its underlying causes. They also depend on the political economy of nutrition policy—including policies relating to food environments and the global food system. The aim of this chapter is to map out the public health dimensions of food and nutrition problems that increasingly assail the world as well as to provide some guidance on the population-based interventions necessary for diet-related diseases to be contained.

The double burden of malnutrition

Malnutrition refers to nutritional excesses of macronutrients and micronutrients as well as deficiencies (WHO 1995). Undernutrition is the result of insufficient intake, poor absorption, and/or poor biological use of the nutrients. This can result in impaired body functions, impaired growth, and underweight. Excess or imbalanced nutrient intakes can result in impaired body functions, as well as overweight and/or obesity. The double burden of malnutrition (DBM) was presented as a 'new paradigm', at the 1992 International Conference on Nutrition (ICN), a member state meeting jointly hosted by the United Nations Food and Agriculture Organization (FAO) and the World Health Organization (WHO). It was subsequently recognized that DBM occurs not only in the same populations, but also in the same households, and even the same individuals (Shrimpton and Rokx 2012). At the population level women are the most affected by DBM, with most low- and middle-income countries (LMICs) having problems of both overweight and underweight women (Jaacks et al. 2015). The most common form of DBM at the household level is stunting in children and overweight/obesity in women (Garrett and Ruel 2005). For individuals the most common form of DBM is overweight and iron deficiency (Zhao et al. 2015). Furthermore, new evidence emerged suggesting that maternal and foetal undernutrition increased susceptibility to overweight and obesity and diet-related non-communicable diseases (NCDs) in adulthood. Consequently, the understanding of the causal links to overweight and obesity evolved to reflect the double burden causality across the 'life course' (Darnton-Hill et al. 2004). Separating the treatment and/or prevention of nutritional deficiencies and excesses was therefore no longer considered sensible.

Most countries are now grappling with multiple burdens of malnutrition, and globally overnutrition is increasing faster than undernutrition is decreasing. Estimates are that at least 88% of countries face a serious burden of either two or three forms of malnutrition, i.e. childhood stunting, anaemia in women of reproductive age and/or overweight in adult women (Development Initiatives 2017). Two billion adults were overweight or obese globally in 2017 (a third being obese), while 815 million people were still going to bed hungry and 2 billion people lacked key micronutrients like iron and vitamin A. Furthermore 155 million children were stunted, and 52

million children were wasted, while 41 million children were overweight. Obesity prevalence more than tripled from 3.2% to 10.8% among men and more than doubled (6.4–14.9%) among women from 1975 to 2014. By comparison, the prevalence of underweight people decreased from 13.8% to 8.8% among men and 14.6% to 9.7% among women (NCD Risk Factor Collaboration 2016). Between 1975 and 2016 the prevalence of moderate and severe underweight in girls decreased from 9.2% to 8.4% and from 14.8% to 12.4% in boys (NCD Risk Factor Collaboration 2017). More than 20 million infants worldwide, representing 15.5% of all births in 2000, were born with low birthweight, 95.6% of them in LMICs (UNICEF/WHO 2004). Accurate monitoring is challenging, since nearly half of the world's infants are not weighed at birth, but this situation does not seem to have improved. Iron deficiency is the most common and widespread nutritional disorder in the world, being common in both high and low-income countries.

Measuring nutritional status

Methods of defining nutritional status and describing the size of nutritional problems have evolved considerably in the last few decades. Until the turn of the millennium the focus of nutrition programme efforts was on child undernutrition, the population estimates of which largely relied on the adequacy of weight-for-age in children under five. These efforts essentially focused on trying to understand the aetiology of the severe forms of undernutrition, kwashiorkor, and marasmus, trying to prove the hypothesis that these were protein deficiency and energy deficiency diseases (Scrimshaw and Viteri 2010). There was little awareness at that time that non-severe forms of malnutrition existed, and that their consequence for a population perspective was of immense importance. During this era, much was achieved in terms of definitions for undernutrition. Moderate malnutrition was defined as between 2 and 3 Z scores, and severe malnutrition was more than 3 Z scores, below the median of the Harvard growth standard (Jelliffe 1966). However, as noted by Waterlow (1973), a deficit in weight-for-age conceals two different conditions, a deficit in height-for-age or 'stunting' and a deficit in weight-for-height or 'wasting'. It is important that these conditions should be differentiated and assessed separately, because they reflect different underlying problems: stunting tends to reflect chronic undernutrition, and wasting, acute undernutrition.

Recognizing the needs for more representative references for child growth and nutrition, WHO developed the WHO International Growth Reference (de Onis et al. 2006), constructed by measuring the growth of cohorts of well-fed children from several nations. This was essentially to demonstrate that in the right circumstances, i.e. healthy environments, children grew similarly independent of their ethnic differences or geographical location. Indeed, this is now the growth standard children of all nations should attain.

In the years since the pioneering work on child undernutrition, it has become increasingly obvious that the burden of malnutrition is changing, with dietary risk factors for overweight and NCDs becoming more and more of a problem. In consequence increasing effort has gone into better defining and measuring overnutrition. Overweight and obesity are most commonly measured in adults with the body mass index (BMI), which is weight divided by height squared. A BMI greater than 25 is regarded as overweight and greater than 30 is obesity. Child overweight is also defined as a weight-for-height greater than +2 standard deviations of the WHO Child Growth Reference (WHO 2017a). The World Health Organization has also recommended BMI cut-offs for overweight and obesity be 23 kg/m^2 and 27 kg/m^2, respectively in Asia, lower than the cut-offs used in Caucasian populations (WHO 2004). Further measures of adiposity include waist circumference and skinfold thickness, but these are more often used for individual than population assessments.

Nutrition and health

Nutritional diseases are caused by both under and overnutrition and affect people throughout the lifecourse. Undernutrition, including foetal growth restriction, suboptimal breastfeeding, stunting, wasting, and deficiencies of vitamin A and zinc, caused 45% of child deaths, resulting in 3.1 million deaths annually in 2011 (Black et al. 2013). Breastfeeding is the most important start to life in terms of feeding patterns (Victora et al. 2016). Appropriate breastfeeding practices prevent child morbidity due to diarrhoea, respiratory infections, and otitis media. Where infectious diseases are common causes of death, breastfeeding provides major protection. Despite these benefits, in 2013, only about two-fifths of infants in LMICs were exclusively breastfed for the first 6 months of life, and three-quarters

were still being breastfed at 12–15 months (Rollins et al. 2016). Rates in high income countries (HICs) are less sure but are much lower at all ages.

At least a third of the world's population, some 2 billion people, are anaemic, many due to iron deficiency, and in resource-poor areas, this is frequently exacerbated by infectious diseases. Maternal anaemia, especially during the first trimester of pregnancy, can be considered as a risk factor for many pregnancy outcomes including low birth weight (Rahmati et al. 2017). High BMI accounted for 4 million deaths globally in 2015, nearly 40% of which occurred in persons who were not obese but overweight (The GBD 2015 Obesity Collaboration 2017). More than two-thirds of deaths related to high BMI were due to cardiovascular disease. Furthermore, Asians at any given level of adiposity have a much greater predisposition to cardiometabolic disorders than Caucasians (Haldar et al. 2015).

Increasingly, diet-related metabolic risk factors and NCDs are becoming the major driving force behind the global burden of disease. NCDs accounted for 64 % of the attributed risk factors for deaths in 2016 (GBD 2016 Risk Factor Collaborators 2017). High blood pressure was the fourth-leading risk factor for both men and women in 1990 and had risen to be the second leading risk factor for men and the leading risk factor for women by 2016. High fasting plasma glucose (FPG) was the third leading risk factor for deaths and the fourth-leading risk factor for disability-adjusted life years (DALYs). Diabetes was the largest source of DALYs attributable high FPG. The global prevalence of diabetes has nearly doubled since 1980, rising to 8.5% in the adult population, with 422 million so affected, three times more than in 1980 (WHO 2016). By increasing the risks of cardiovascular and other diseases, diabetes, and high FPG caused 3.7 million deaths, with 43% of these occurring before the age of 70 years. The percentage of deaths attributable to high FPG or diabetes that occurs prior to age 70 is higher in LMICs than in HICs.

Systematic reviews find that red meats, processed meats, sugar-sweetened beverages, high glycaemic load foods, transfats, and sodium are the principal dietary factors that increase the risk of cardiovascular disease and diabetes (Micha et al. 2017).

Changing dietary patterns

Globally, food consumption per person measured as dietary energy intake, increased by 15% in the 30 years up to 2000 (Kearney 2010). In the same period annual meat consumption in LMICs rose from 10 kg to 26 kg per person (WHO/FAO 2003). Global consumption of milk and dairy products also doubled to 45 kg, and the average global supply of fat increased by 20 g per capita per day. The type of carbohydrate in the diet also changed, with decreases in complex carbohydrates such as starchy foods (for example, whole grain cereals and legumes) and an increase in refined sugar. The average global consumption of fish increased from 13.4 kg per capita in 1990 to 16.3kg per capita in 1999 (FAO 2003). The concept of this 'consumption' is more related to food purchased than intake, as it doesn't take into consideration food waste. Food lost and wasted along the way from field to fork may be as much as a third, amounting to about 1.3 billion tonnes per year (FAO 2011).

WHO recommends that adults and children should maintain a reduced intake of free sugars over the life course, and this should be less than 10% of total energy intake (WHO 2015). Global assessments of sugar intake as a percentage of energy intake range from 20.0% to 38.4% in young children and 13.5–24.6% in adults (Newens and Walton 2016). Various systematic reviews and meta-analyses provide evidence that consumption of sugar-sweetened beverages (SSBs) (Malik et al. 2006) or free sugars (Te Morenga et al. 2012) promotes weight gain in adults and children. Per capita sugar consumption is strongly associated with the prevalence of diabetes mellitus in a 165-country analysis, with the strongest association found in the Asia region (Weeratunga et al. 2014). Another problem is that many processed foods have a high glycaemic index (Fardet et al. 2017), with blood sugar levels remaining high for a long period after the food is eaten. Consumption of higher glycaemic index foods are associated with increased risk of type 2 diabetes (T2D) (Bhupathiraju et al. 2014) and coronary heart disease (CHD) (Fan et al. 2012).

The proportion of energy contributed by dietary fats exceeds 30% in the HICs, and in nearly all other regions this share is increasing, even though the WHO recommendation is for not more than 30% (WHO/FAO 2003). Thinking has now changed however, and fat intake is regarded as less important in the genesis of obesity and cardiovascular disease with calls to revise the dietary guidance (Willett 2011; Harcombe et al. 2016). Contrary to popular commentary regarding the fat intake being bad for health, a recent

dynamic time series analysis of US and global population data sets suggests that while increases in carbohydrate consumption are associated with increasing weight, increases in fat consumption are associated with decreasing weight (Riera-Crichton and Tefft 2014). Similarly, a cohort study in 18 countries from five continents has also found that high carbohydrate intake was associated with higher risk of total mortality, whereas total fat and individual types of fat intake were related to lower total mortality (Dehghan et al. 2017). Alongside this changing understanding of the impact of fat and carbohydrate (particularly sugar) intakes on health has been increasing evidence for the role of 'ultra-processed' foods in contributing to diet-related NCD risk (Fardet 2016; Fiolet et al. 2018).

It is increasingly recognized that what is eaten is as important as how much is eaten in the causality of obesity and cardiovascular disease. Traditional thinking that 'eating too much' and 'moving too little' are the causes of the rising global obesity problem is increasingly coming under scrutiny (Shrimpton et al. 2017). Average adult weight began to increase by 1.5 kg a year in the early eighties in the United States and the main drivers were the consumption of processed foods, and especially of potato chips and SSBs (Mozaffarian et al. 2011). This suggests that relatively minor changes in diets—for example, marginal increases in energy intakes due to increased discretionary food intake—can have significant impacts on body weight and health over the long term.

The food environment

These dietary changes have occurred during a time of systemic changes to the food environments in which people make decisions about what—and how much—they eat. The food environment acts as an important interface between the wider food system and peoplés food acquisition and consumption through continuous and complex interactions between external and personal food environments. The external food environment domain relates to the world of opportunities and constraints that exists within a given context, and includes exogenous dimensions such as food availability, prices, vendor and product properties and marketing and regulation. The personal food environment domain includes a set of endogenous dimensions including food accessibility, affordability, convenience, and desirability (Turner et al. 2017).

Processed foods now account for 80% of country food sales (Mazzocchi et al. 2012), that is foods sold through retail outlets. Ultra-processed products are becoming dominant in the global food system, including in LMICs where they have become ubiquitous, especially in urban areas (Igumbor et al. 2012; Monteiro et al. 2013). These foods are formulations of several ingredients which, besides salt, sugar, oils, and fats, include food substances not used in culinary preparations in the home, such as flavours, colours, sweeteners, emulsifiers, and other additives. They contribute almost 60% of the energy and 90% of added sugars consumed by the USA population (Martínez Steele et al. 2016). Chemical food additives are used to make processed foods look, smell, and taste better, as well as to improve their shelf life. These include a large assortment of colourings, preservatives, antioxidants, emulsifiers, stabilizers, anticaking agents, and flavour enhancers. In 2000, the food industry spent US$20 billion on such additives, and the average consumption was 7 kg per person a year in industrialized countries (Millstone and Lang 2003).

Changing food systems

Changes to food environments reflect broader changes to food systems, that have revolutionized how food is produced, processed, and marketed. Global food production has outpaced rising demand based on population growth rates during the last four decades (FAO 2002). The number of farms globally is around 570 million, and of these 83% are small farms of less than two hectares (Lowder et al. 2016), which operate about 12% of the world´s land. Despite the population almost doubling, the per capita supply of energy from food for human consumption rose by just over 20% between the early 1960s and the late 1990s. The greatest growth came from increases in the production of wheat, vegetable oils, sugar, and meat.

The increase in global food production has been largely attributed to the green revolution (Pingali 2012). The production of cereal crops tripled in the last 50 years with only a 30% increase in land area cultivated. Using petroleum-based fertilizers and chemical pesticides, expanded irrigation, and genetically modified disease-resistant cultivars, cereal production (wheat, rice, maize) doubled in Asia between 1970 and 1990. This success was concentrated in areas where irrigation water, infrastructure (roads) and access to markets (input and output) as well as credit were well developed.

In areas without these conditions, such as in most of Africa, the impact of the green revolution was less impressive.

Of the 446 million small farms, the majority (87%) are in Asia, and only 8% are in Africa and 1% in the Americas. About a half of small farms are pre-commercial, i.e. not benefitting from productivity enhancing technologies, financing, and market access. While these small farms of the peasant food web provide 70% of total food eaten globally (ETC Group 2015) and harvests 60–70% of food crops from 20% to 30% of arable land, the larger farms of industrial agriculture food system provide 30% of all food consumed globally and uses 70–80% of world's arable land. Even where the green revolution was successful in raising productivity this was concentrated in the richer larger landholders, as the poorer farmers of the peasant food web could not afford to pay for these inputs. The green revolution thus gave impetus to the development of agribusiness (Engdahl 2007), designed to increase the flow of food crops from the places of production through the food system, to the place of consumption.

The number of actors providing the inputs needed to achieve increased production through the industrial agricultural system is very limited (ETC Group 2013). A few big multinational conglomerates, including Monsanto and DuPont, Syngenta and Bayer, Dow, and BASF, control 75% of all private sector plant breeding research, 60% of the commercial seed market and 76% of global agrochemical sales. About a third of global cereal production and just over 90% of soybean production is used to feed farm animals, mostly in factory farms of the industrial agriculture food system (FAO 2002).

Around 56 billion land animals are estimated to be reared and slaughtered for human consumption annually (Koneswaran and Nierenberg, 2008). These estimates vary considerably however, largely depending on terminology and definitions used. It is agreed that factory farms are the most rapidly growing system of farm animal production (FAO 2009), providing 72% of poultry, 43% of eggs, and 55% of pork globally. Furthermore, capture fisheries production increased from 69 million to 93 million tonnes during the last three decades, while world aquaculture production increased from 5 million to 63 million tonnes (World Bank 2013). Aquaculture will provide close to two-thirds of global food fish consumption by 2030 as catches from wild capture fisheries level off and demand from an emerging global middle class, especially in China, substantially increases

Food is now a major component of international trade, accounting for 10% of all global trade (FAO 2011a), and the aggregate value of agricultural exports passing through the international food system was expected to reach a record US$1.29 trillion in 2011. The amount of food calories traded on the international market is about 20% and had more than doubled between 1986 and 2009 (D'Odorico et al. 2014). Much of the increases in global food trade have been in highly processed commodities. Since the early seventies and the development of the Washington Consensus on the conditionality for structural adjustment programmes (SAPs) from the World Bank, and the 'standard prescription' by the International Monetary Fund (IMF), LMICs have been increasingly encouraged to liberalize trade and investment, privatize national industries, and reduce state support to local agricultural production (Weis 2007). The Washington Consensus also bolstered the global free trade negotiations under the General Agreement on Tariffs and Trade (GATT), which eventually resulted in the creation of the World Trade Organization (WTO) in 1994. Alongside this, multilateral, regional, and bilateral trade agreements, such as the North American Free Trade Agreement (NAFTA), have proliferated in the past 30 years.

The WTO, World Bank, and IMF are thus key institutions governing trade in the modern global food system. All these institutions have mandates that include food security to some extent—but this inclusion has been along economic lines, focused on calorie availability at the national level, and paying little attention to inequalities and sociocultural aspects of food production and distribution (Rosset 2006; Margulis 2013). Another key actor in global food governance is the Codex Alimentarius Commission, which sets food standards, including approval for use of food additives. The Codex is recognized by the WTO as an international reference point for the resolution of disputes concerning food safety and consumer protection, thus lending it greater authority (Halabi 2015). However, while Codex is a member state organization, under the WHO and UN FAO, it is also a standards-setting body with open membership. This means that industry actors can act as formal observers and has resulted in standards that often preference trade interests over public health (Downes 2014).

Growing industry concentration has led to a situation where just a few companies control large shares of the flow of food through the global food system (FAO 2002). In 2003 just four firms controlled 73% of the global grain trade (Murphy et al. 2012). Furthermore, these multinational

corporations are highly diversified and integrated both vertically and horizontally; for example, Cargill, ADM, and Bunge not only account for more than 60% of total financing of soy production in Brazil, but they also provide the seed, fertilizer, and agrochemicals to the growers, and subsequently buy the soy and store it in their own facilities (Murphy et al. 2012). In the USA Cargill is number one in terms of domestic grain handling, as well as grain and soybean exports but also the second largest compound feed producer and the number three turkey producer. Policies of trade liberalization have facilitated the rising availability and consumption of relatively cheap meat, dairy products, and processed foods in LMICs (Thow and Hawkes 2009). Imported foods tend to be cheaper because of continued state support to the industrial agriculture system in HICs, and their dumping of cheaper food commodities onto the world market.

Notwithstanding the increasing production of food globally, food prices have risen sharply since 2006, impacting most negatively on the poor. The main drivers of food price rises are the increasing use of land for biofuel production in the face of rising energy costs, and greatly increased speculative acquisition of land, as well as financial speculation on food futures (McMichael 2012). Speculative acquisition of land, sometimes termed ‘land grabbing’ authorizes large-scale removal of rural populations from (often) ancestral lands to install ‘agriculture without farmers’, i.e. agro-industrialization. It sacrifices land and its inhabitants in favour of what is a necessary global good (food yields, green fuels, and carbon offsets). For example, in Colombia between 2001 and 2005, 263,000 peasant families were expropriated from 2.6 million hectares by agrobusiness and/or paramilitaries interested primarily in palm oil development. (McMichael 2012).

Another recent and major contributor to rising food prices is financial speculation in food. The deregulation of commodities derivatives markets in 2000 as part of financial liberalization allowed large institutional investors to enter these markets. Between 2003 and 2008 commodity index holdings increased from $13 billion to $317 billion (McMichael 2012). Already in 2006, Merrill Lynch Wealth Management and Financial Services estimated that speculation was causing commodity prices to trade at 50% higher than if they were based on fundamental supply and demand (De Schutter 2010). The increase of the agricultural commodities futures between March 2003 and March 2008 was accompanied by price increases during the same period

for coffee with 167%, for soybean oil with 199% and for wheat with 314% (Kerckhoffs et al. 2010).

Global food retail sales are about US$4 trillion annually, with supermarkets accounting for the largest share of sales (Meade 2017). The urban demand for food in LMICs is expected to more than double in the next decade. It will be responsible for almost the entire growth in global food demand, spiking from about 40% to some 60% by 2050. The emergence of supermarkets in LMICS is leading to a radical change in the global food marketing and distribution system (Reardon et al. 2015). Structural changes in the food distribution system, which took 50 years to unfold in the United States, have taken place in little more than a decade in Latin America. In China, where no supermarkets existed in 1989, annual supermarket sales were US$100 billion in 2008 (Reardon and Gulati 2008). Unlike HICs, where supermarkets are often the principal, if not only, source of fruits and vegetables (Larson et al. 2009), supermarkets in LMICs are often distribution channels for cheap processed foods including less than healthy snacks and 'junk' food, as well as being venues for fast food chains.

Given the changing nature of the food system one of the greatest challenges to improving nutrition is how to deal with the burgeoning private sector. The food industry is now a massive business, with ten big food and beverage companies generating revenues of more than US$1.1billion a day (OXFAM 2013). Together they are part of an industry valued at US$7 trillion, larger than the energy sector and representing roughly ten percent of the global economy. Although spending on processed foods is still lower in LMICs (US$143 per capita per year in middle-income countries and US$63 per capita in low-income countries), it is growing at 28% and 13% a year respectively in those country groups.

The political economy of food and nutrition

The economic consequences of the DBM across the life course are massive. Estimates are that more than 200 million stunted children under 5 years of age in LMIC countries that survive growth failure in the first 1,000 days, are not developing to their full potential, and that this is associated with more than a 20% deficit in their income as adults (Grantham-McGregor et al. 2007). It is hard to put a single figure on this, but in comparison with the costs of over nutrition they are likely to be small. Current trends project 65

million more obese adults in the United States and 11 million more obese adults in the United Kingdom by 2030, consequently accruing an additional 6–8.5 million cases of diabetes, 5.7–7.3 million cases of heart disease and stroke, 492 000–669 000 additional cases of cancer, and 26–55 million quality-adjusted life years forgone for United States and UK combined (Wang et al. 2011). Combined medical costs associated with treatment of these preventable diseases are estimated to increase by $48–66 billion/year in the United States and by £1.9–2 billion/year in the UK by 2030. Over the next 20 years, the cost of treating NCDs and cumulative output losses globally are likely to be at least US$30 trillion and US$47 trillion, respectively, representing 48% and 75%, respectively, of global GDP in 2010 (Bloom et al. 2011). Of course, the great majority of these NCDs are diet-related.

At the turn of the millennium the prospects for eliminating young child malnutrition were considered grim. An assessment done by the World Bank and UNICEF (Gillespie et al. 2003) revealed that nutrition was improving slowly in some regions but was stagnant in others and was often side-lined in poverty agendas despite its potential to improve health, mental development, and productivity. Although nutrition professionals broadly agreed on key interventions and on success factors for implementation, this was not reflected in action. Few large-scale programmes were rigorously monitored and evaluated and inadequate capacity to tackle malnutrition was a major factor limiting progress.

The publication of the Lancet Nutrition Series in 2008, including an article with a package of low cost efficacious interventions for tackling maternal and child undernutrition (Bhutta et al. 2008), stimulated a tremendous increase in political commitment to the reduction of child undernutrition. In consequence most development agencies revised their strategies to address undernutrition and focused on the 1,000 days during pregnancy and the first 2 years of life. National commitment in LMICs grew, donor funding rose, and civil society and the private sector were increasingly engaged. However, despite this ‘awakening’, progress in tackling stunting was still considered insufficient 5 years later (Black et al. 2013). In 2012, the World Health Assembly endorsed a comprehensive implementation plan on maternal, infant, and young child nutrition which specified six global nutrition targets for 2025. The first target is a 40% reduction in the number of children under-5 who are stunted. The global prevalence of stunting in

children under-5 declined 36% during two decades—from an estimated 40% in 1990 to 26% in 2011 (UNICEF 2013), hence the likelihood of a further 40% reduction by 2025 seems remote.

Translating the evidence, interest, and government concern regarding nutrition into action on the ground has proved challenging—often as the result of politico-economic challenges (Balajaran and Reich 2016). One such challenge is that the nutrition system and community are fragmented from global to community level. Among the various subgroups at the country level are clinic-based medical nutritionists, academic nutritionists, development economists, and planners, social scientists, public health nutritionists, and agricultural specialists. Building coalitions across these different groups is challenging and time-consuming. Furthermore, this multiplicity of stakeholders creates multiple narratives concerning nutrition approaches, which can lead to contention and rivalry. All these challenges are compounded by a limited capacity among nutritionists, be it to engage in the broader political dynamics of managing nutrition policy or the delivery of interventions by multiple actors/sectors.

The private sector must surely play a role in controlling the malnutrition problem, but this will require balancing public health needs with commercial interests and managing conflicts of interest requires transparent systems and mechanisms (Hawkes and Buse 2011). Efforts to achieve some balance have been developed though the scaling up nutrition (SUN) initiative (Bezanson and Isenman 2010), with countries increasingly looking to the private sector to join national SUN multistakeholder committees. Recent evaluations of SUN suggest that it is still far from being successful in achieving any impact however (Mokoro 2015). The challenge facing policymakers trying to integrate business into national nutrition strategies remains and mistrust and opposition to the private sector are the hardest challenges. Until now the SUN ‘movement’ has been largely focused on maternal and child undernutrition, but whether and how it can evolve to include overnutrition and the metabolic and NCDs remains to be seen, as the potential for conflict of interest are obviously enormous.

Multinational retailers have introduced into LMICS the types of supply chain seen before in HICs, based around tight vertical coordination, centralized purchasing, and sophisticated marketing (Mazzocchi et al. 2012). They accelerate the rate at which local firms adopt these strategies and tailor them to local needs, and in doing so provide employment and generate

income locally. Most of the profits however still revert to the head office of the chains located in HICs (Hawkes 2005). These trends risk eroding the more traditional access to fruit in urban areas of LMICs, such as in South Africa for example, where it is primarily through the informal market; in particular, wet markets or stalls and street vendors. Specific policy opportunities that could increase access to fruit and vegetables in South Africa and other LMICs are: targeted support for periurban farmers to access urban markets (e.g. transport); including food production considerations in initiatives for urban greening; and, initiatives that could increase access to, or incentivize the sale of, fresh fruit and vegetables by street vendors (Thow et al. 2017)

The food industry spends at least US$ 40 billion a year globally on advertising processed foods (Millstone and Lang. 2003). The evidence indicates that unhealthy food and beverage marketing increases dietary intake and preference for unhealthy food and beverages. Marketing of unhealthy food and beverages increased dietary intake and influenced dietary preference in children during or shortly after exposure to such advertisements (Sadeghirad et al. 2016). Exposure to child-targeted fast food TV advertising is positively associated with fast food consumption among children of pre-school age (Dalton et al. 2017). Trade liberalization is considered to be driving the NCD epidemic in Asia (Baker et al. 2014). Evolving layers of the international and regional trade regimes have facilitated increased market penetration by transnational tobacco, alcohol, and ultraprocessed food corporations and thereby driven consumption of these unhealthy commodities in Asia especially.

Challenges to taking action

Nutrition has been identified as a ‘chosen issue’, meaning that champions are required to put it on the policy agenda (Garrett et al. 2011). Moreover, the implementation of multisectoral approaches for maternal and child undernutrition (MCU) improvement demands strong and sustained support from high levels of government (Levinson and Balarajan 2013), and this is no different for overnutrition. Accelerating progress in nutrition through multisectoral approaches requires building leadership at nationally and locally.

The lack of a natural institutional home in government is a challenge, as nutrition doesn't fit cleanly into any single government agency, with health or agriculture usually nominated as a 'home' agency—but both departments are usually unable to lead cross-sectoral action across government. To surmount this problem many countries have created a 'home' for nutrition in suprasectoral bodies such as the prime minister's office or the ministry of planning. Giving high profile leaders—such as Prime Ministers and Mayors—a central role in driving initiatives has been shown to be a key factor in bringing different actors together to collaborate towards NCD prevention goals (Meiro-Lorenzo et al. 2011).

Nutrition capacity is often weak in many countries and in LMICs especially. This is largely related to the absence of a common understanding of the malnutrition problem (Heaver 2005). This lack of understanding as well as the relatively recent development of public health nutrition (PHN) science have undoubtedly contributed to the shortage of professionals capable of developing population-based approaches for the prevention of all forms of malnutrition as opposed to (or in addition to) a cadre capable of treating the consequences in individuals. Indeed, in most African countries nutrition programmes and interventions are led by nurses whose nutrition knowledge is generally very limited. Typically, other development actors look to the health sector for nutrition guidance, while health sector workers' nutrition training is all too often woefully outdated and clinical.

A consensus is growing that a robust and knowledgeable workforce is essential for PHN policy implementation (Yngve et al. 2012). How to build that capacity is the question that still needs to be answered, especially in LMICs. A hybrid distance learning model for PHN workforce managers' in-service training is urgently needed, especially in LMICs (Shrimpton et al. 2016), and unless increased priority and funding is given to building capacity for SUN programmes in LMICs, MCU rates are likely to remain high and nutrition-related NCDs to escalate.

The World PHN Association has placed considerable emphasis on improved definition of the nutrition capacity and how to build it since its inception in 2008. A competency framework was first developed (Hughes et al. 2012) which described the core functions of PHN practice, and the work done at different levels of the public health system. Subsequently a nutrition capacity assessment framework was proposed (Shrimpton et al. 2013) to guide the systematic assessment of capacity development needs at system,

organizational, workforce, and community levels. While nutrition has to be everybody's business at the district level, somebody has to be in charge. That is the role proposed for the public health nutritionist.

Another serious challenge that faces nutrition is demonstrating the effectiveness of policies and programmes. Improving nutrition in practice is complicated and context specific, since it requires careful strategic planning, informed by the situational analysis and prioritization of programmatic interventions to be funded with limited resources (Balajaran and Reich 2016). There is a growing repertoire of efficacious nutrition interventions for maternal and child undernutrition but translating that knowledge into practice and demonstrating tangible results at scale is still difficult to achieve (Leroy and Menon 2008). It is easier for academic experts in nutrition to get funding for carrying out research than for programme evaluations.

While intervening in the first 1,000 days is critical, addressing the DBM requires expanding the focus of nutrition interventions to cover the rest of the life course and the food system (Fig. 2.8.1). The importance of employing multisector policies and interventions for improving nutrition outcomes has been widely agreed during this last decade (World Bank 2006). Indeed, these nutrition-specific and nutrition-sensitive interventions need to be continued across the school years into adulthood and the workplace (Shrimpton and Rokx 2012). Moreover, in order to tackle the double burden a range of policy interventions and programmes are needed to address the overall food environment (Shrimpton et al. 2016) and concerted efforts are needed from the health, education, agriculture, industry, social protection, and water and sanitation sectors as shown in Figure 2.8.1.

The nutrition-specific interventions directed at immediate levels of causality are mostly delivered through the health sector, while nutrition-sensitive interventions directed at the underlying and basic levels of causality are often delivered through other sectors such as education, agriculture, water and sanitation, and social welfare. Scaling up the priority nutrition-specific interventions through the health sector to cover 90% of the population in the 36 countries with 80% of the global stunted children will only reduce stunting by 20% (Bhutta et al. 2013), still short of the WHO CIP target for 2025. Scaling up the nutrition-sensitive interventions through other sectors is therefore required to achieve these MCU targets and perhaps as important, do so in a sustainable way. Although the evidence base doesn't yet permit precise estimation of the contribution of nutrition-sensitive

interventions to stunting reduction, early indications are that social protection, agriculture, and water and environment, and public health can all greatly contribute to the acceleration (Fanzo et al. 2013).

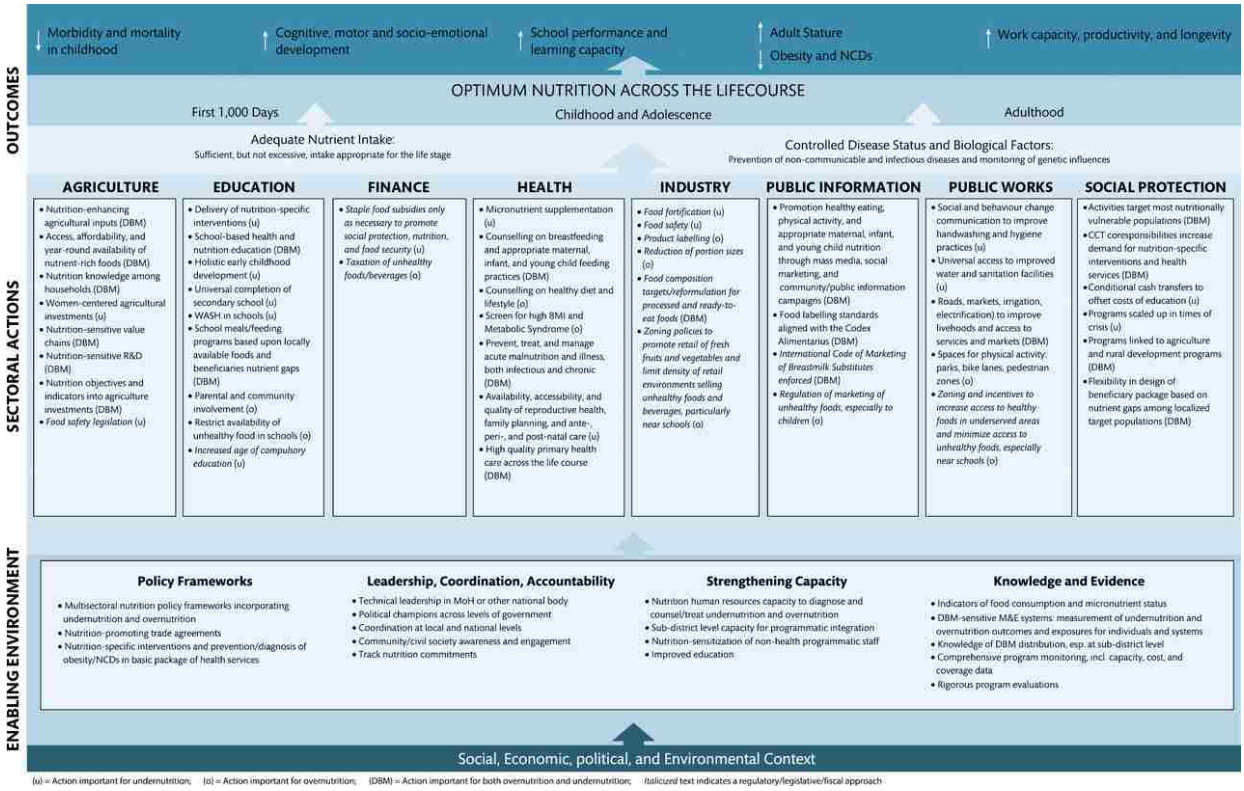

Fig. 2.8.1 Framework of sectoral actions and systems strengthening efforts needed for a multisectoral response to the double burden of malnutrition.

Reprinted from Shrimpton R, Mbuya NK, Provo AM (2016) 'The Double Burden of Malnutrition in East Asia and the Pacific: Evidence and Lessons for a Multisectoral Response'. Washington: World Bank under a CC BY 3.0 IGO license.

The estimates of impact of the various packages of nutrition interventions assumes that all are delivered together. Rather than joint programme implementation, the various sectors need to converge their programme interventions to be delivered together as a package. This process is essentially the responsibility of local government and is facilitated by decentralization (Shrimpton 2002). Community-based programmes are of importance here, especially if they have the essential elements of community ownership, adequate population coverage, targeting, and central support for supplies and training (Mason et al. 2006). The promotional activities, which

aim at ensuring optimal growth of the foetus/infant from conception through to 2 years of age, i.e. the first 1,000 days, typically include: treating maternal anaemia; treating infections such as intestinal parasites and avoiding/treating malaria; monitoring growth of the infant; promoting breast feeding and adequate complementary feeding; using oral rehydration for diarrhoea, and getting children immunized.

In a typical community-based programme, community 'mobilizers' take on the task of looking after households in their neighbourhood, allowing whole communities to be mapped and covered. A certain level of intensity of effort must be ensured, with optimal ratios of not more than 20 mobilizers per facilitator and not more than 20 households per mobilizer. If these levels of intensity of effort with a sufficiently wide coverage are not ensured, no impact will be seen in the population, and the resources invested will be largely lost. A key challenge for scaling up such community-based programmes lies in institutionalizing and mainstreaming community participation (Lehmann and Sanders 2007).

As no single sector alone can solve the problem of undernutrition, neither can a health-centric approach reverse the growing trend of overnutrition. Multiple sector contributions are needed, and the necessary actions range from national and district level policies to creating supportive community environments and supporting individuals to change their behaviours. National level political support—through taxation, regulation, and/or subsidization—is necessary to ensure social environments that support healthy decisions as the default. Interventions are needed beyond the realms of 'self-will': ensuring that physical activity is facilitated and easily available and access to quality diets is affordable, without the promotion of unhealthy products and habits through the media. The education sector has an important role to play in nurturing the development of children who graduate from school with adequate life skills and appropriate habits that help them avoid these risks in adulthood. The health sector must do more to deliver the messages and screening that can contribute to primary and secondary prevention, particularly for adults.

There is clear evidence that policy intervention that fosters a food environment in which the healthy choices are more available and affordable than the unhealthy choices, and in which marketing and point of sale incentives do not preference unhealthy foods, can support consumers to make healthier choices (Hawkes et al. 2015). Macro, or environment-

focused, policy intervention can help to correct for existing incentives in food environments which incentivize the purchase of highly processed (and highly profitable) unhealthy foods and beverages. For example, fiscal policy interventions, including taxes and subsidies, can help to incentivize consumption of healthier, rather than unhealthy foods (Thow et al. 2018). Similarly, nutrition labelling interventions are critical in supporting healthier point-of-purchase decision making, by clear external labelling detailing the internal properties of the foods (Cecchini and Warin 2016).

The WHO recommendations for childhood obesity prevention programmes include key points which have population-wide relevance (WHO 2016a). These recommendations include: use a mixture of 'top-down' and community-based actions, employ a range of policy instruments, establish cross-sectoral platforms and a multisectoral approach; promote interventions across a range of settings, including early childcare settings, schools, workplaces, and community organizations; and leverage legislative and financial tools to ensure availability and affordability of healthy foods and physical activity opportunities. Similarly, for reducing the risk of chronic NCDs, WHO has found multicomponent interventions that are adapted to the local context to be the most successful (WHO 2013a, 2013b). Interventions that used the existing social structures of a community, such as schools or the weekly meetings of older adults, reduced barriers to implementation. Effective interventions invariably involved participants in the planning and implementation stages, such as involving the workers themselves in workplace interventions, and the leaders of the range of civil society organizations in the community.

In 2015 the United Nations adopted a set of goals to be achieved by 2030 with the aim of ending poverty, protecting the planet, and ensuring prosperity for all as part of a new sustainable development agenda (UN 2015). While considerable progress has been made over the past decade across all areas of development, the pace of progress observed in recent years is insufficient to fully meet the sustainable development goals (SDGs) and targets by 2030 (UN 2017). One of the seventeen SDGs is directly related to food and nutrition, namely SDG 2 which is to end hunger, achieve food security and improved nutrition, and promote sustainable agriculture. While some progress has been made to reduce hunger and malnutrition, it is not enough to meet the goal. Failure to achieve SDG2 will also make other SDGs difficult to achieve, since the pervasive negative influence of our

current food system endangers many others (Shrimpton 2017). The SDGs provide an exciting opportunity to achieve global nutrition targets while catalysing other development goals through 'double duty' actions (WHO 2017b). These include interventions, programmes and policies that have the potential to simultaneously reduce the risk or burden of both undernutrition (including wasting, stunting and micronutrient deficiency or insufficiency) and overweight, obesity, or diet-related NCDs.

Learning from success

Examples of successful programmes are not easily found, but experiences gained in Brazil with undernutrition and France with overnutrition offer some important insights.

In Brazil the Bolsa Familia Programme (BFP) is part of the National Food and Nutrition Security System (SISAN), which has evolved over the last two decades to become a very effective large-scale multisectoral nutrition programme. The principal sectors participating in SISAN include the Ministries of Social Development, Health, and Education. At national level SISAN is overseen by the National Council on Food and Nutrition Security (CONSEA). CONSEA is a deliberative body with two-thirds of its members made up of civil society, and that is linked to the President's Office. Coordination and implementation of SISAN is carried out by an interministerial chamber on food and nutrition security (CAISAN) which is located in the Ministry of Social Development (Chmielewska and Souza 2011).

The BFP targets the mothers and children of poor families across Brazil, with some 12 million families and 48 million beneficiaries in 2010 (Lindert et al. 2007). The conditionality of BFP includes either school attendance of children aged 5–18, or regular health check-ups for mothers and their children aged under 5 years of age. At the municipal level there are councils and committees that oversee the conditionality requirements of BFP, with the creation of registries of poor families (Cadastro Unico) that are requirements for a family to become BFP beneficiaries. The delivery platforms at the municipal level are the family grant that is dispensed through the banking system based on the family being in the 'Cadastro Unico'. The conditionality of the BFP through the health system includes regular pre- and postnatal care, growth monitoring, immunization, and participation in nutrition

education seminars. These services are largely provided through the Family Health Programme (Programa de Saude da Famila or PSF) of the Ministry of Health. Together, a doctor, nurse, nurse auxiliary, and four to six community health workers (CHW) comprise a multidisciplinary family health support team working in health units in defined geographic areas covering no more than 5,000 residents. (Harris and Haines 2010). There are some 250,000 CHWs. These CHWs must live in the area they work, are responsible for up to 120 families in a defined area and perform home visits to each family once a month.

The PSF provides primary healthcare services in 95% of all 5,564 municipalities, covering 55% of the population or some 85 million people. Coverage of PSF is not universal as it is targeted at poorer areas. Since 2008 the PSF has included a nutritionist in the family health support teams to strengthen nutrition capacity (Jaime et al. 2011). The SISAN also includes the school meal programme (Programa Nacional de Alimentaçâo Escolar or PNAE) through the Ministry of Education, and the Food Acquisition Programme (FAP) through the Ministry of Social Development. There is a requirement that 30% of food used in schools be locally produced, and the Ministry of Agriculture oversees the production, with funds transferred to municipal governments. The FAP primary focus is on small farm families and gives special attention to native fruits and places a high premium on diversified production and consumption by small producer families. School meals are required to be healthy, using fruits and vegetables produced by local farmers and minimizing the use of ultra-processed foods.

The interventions delivered through the various delivery platforms of SISAN including the BFP, PSF, FAP, and PNAE are largely targeted at mothers and their children in poor families. The BFP monthly cash transfers range from $US7 to US$45 per family depending on eligibility (very poor and moderately poor). The health conditionality means that BFP beneficiaries are most likely going to be PSF clients. The PSF CHW’s primary concern is maternal and child health: they provide counselling on maternal and infant and young child feeding, ensure adherence to micronutrient supplementation and immunization, as well as provide guidance on oral rehydration in the treatment of diarrhoea as appropriate. Increasingly CHWs are involved in curative care, triage, and referral to the health unit and health promotion for chronic diseases.

The impact of the various component parts of the SISAN has been quite remarkable in the last decade. The BFP has contributed to reduction of poverty with those on less than US$ 1.25 a day falling from 25.6% in 1990 to 4.8 percent in 2008. Estimates are that the BFP contributed to about 35% of the reduction of the extreme poverty gap. Although there is limited rigorous evidence that the BFP resulted in improved nutrition outcomes (Martins et al. 2013), there is considerable ecological evidence that it contributed to national reductions.

National stunting rates in young children fell from 37.1% in 1974–5 to 7.1% in 2006–7, accompanied by a narrowing of the difference in stunting rates between poor and rich quintiles. The steepest decline was in the last 10 years of that period (Monteiro et al. 2010). In the Northeast of Brazil, the prevalence of child undernutrition fell by one-third between 1986 and 1996 and by three-quarters between 1996 and 2006 (de Lima et al. 2010). The improvements in the first period were mostly associated with improvements in maternal schooling and in water and sanitation coverage, whereas in the second period increasing purchasing power of the poorer families as well as maternal schooling were the strongest associations. Quite remarkably the median duration of breastfeeding in Brazil increased from 2.5 months in 1970 to 14 months in 2006–7 (Victora et al. 2011). Furthermore, it seems likely that PSF has also contributed to the dramatic decreases in infant mortality seen in Brazil in the last few decades (Aquino et al. 2009)

In France, the ‘Ensemble Prévenons l’Obésité Des Enfants’ (EPODE) was first developed in 2003, with the aim to reduce the prevalence of obesity in children under 12 years of age. The institutional arrangements include a central coordination in the Ministry of Health in Paris which liaises with the office of the Mayor in the cities that are involved, where there is a local project manager that works with a local steering committee. EPODE is a large-scale, coordinated, capacity-building approach for communities to implement effective and sustainable strategies to prevent childhood obesity (Borys et al. 2011). EPODE is designed to involve all relevant local stakeholders in an integrated and concrete prevention programme aimed at facilitating the adoption of healthier lifestyles in everyday life (Van Koperen et al. 2013). The delivery platforms include local crèches, health clinics, sports facilities, cultural associations, supermarkets, restaurants, school catering services, school recreation facilities, local parks, and gymnasiums. The activities developed and supported include advocacy and social

mobilization through local media campaigns, together with capacity building and coaching of local actors, as well as the monitoring and evaluation of these activities.

The initial evaluations of the first ten EPODE cities gave encouraging results with ten to 20% reductions in obesity prevalence (Romon et al. 2009). EPODE now extended to nearly 1.8 million inhabitants in 167 French cities, 20 cities in Spain, and 8 cities in Belgium. In June 2008 the first EPODE Mayors' Club European congress was held. Success to date is measured by a large field mobilization in the pilot cities and by the encouraging reduction of the BMI of children in France within the pilot cities (European Public Health Alliance 2008).

The sale of sugary soft drinks and vending machines was also banned in all schools across France. A tax on sugary soft drinks was introduced in 2012, which has led to companies making demands at the EU for evidence of the impact of such taxes. The resulting study found that food taxes achieve a reduction in the consumption of the taxed products and, in some cases, product reformulation aimed at reducing the sugar, salt, and fat levels of the product. It is also found that product substitution takes place, both through an increase in the consumption of taxed products from cheaper brands and non-taxed or less-taxed product substitutes. To what extent such changes in consumption lead to public health improvements was still considered inconclusive however (Ecorys 2014).

Conclusion

Shifting the paradigm for addressing the DBM will require attention to the common drivers of malnutrition. In particular, translating the science into interventions that support and empower people to consume diets of high nutrition quality. The DBM is not two separate problems, but the product of inadequate *access to affordable, quality* sufficient foods. However, transitioning to a food system that delivers foods of high nutritional quality across the population will require addressing the politico-economic factors that shape food production, processing, distribution, and retail. It will also require re-visioning nutrition interventions to consider implications for undernutrition as well as risk factors for overweight and NCDs. For example, programmes like Bolsa Familia and the Mexican Opportunidades have been associated with weight gain and consumption of sugar and SSBs

(de Bem Lignani et al. 2011). To address these global challenges adequately, a key enabler will be strategic investment in PHN capacity at the local, national, and global level. Among the key aims should be promoting exclusive breastfeeding and adequate complementary feeding in children up to 2 years of age, as well as promoting the local production of fruits and vegetables and increasing their availability in local markets and reducing the supply of ultra-processed foods.

Climate change and human health

Alistair Woodward and Alex Macmillan

Introduction to the environment and climate change

This chapter aims to introduce readers to the basic science underlying climate change, to explore the links between climate change and health, and examine the implications of this knowledge for public health policy and practice.

As a start, readers are invited to check their understanding of climate science against the multiple-choice questions in Box 2.9.1. (The answers are shown at the end of the chapter.)

The Earth has an average surface temperature suitable for life that is the product of a number of natural influences on the balance of radiation (radiative 'forcing' at the top of the atmosphere). These include solar activity (the amount of energy produced by the sun), the tilt and orbit of the planet, volcanic activity that injects gases and ash into the upper atmosphere, other dusts and aerosols that block incoming solar radiation, and the amount of reflection ('albedo') by clouds, ice, and snow. Also important is the concentration of so-called 'greenhouse' gases. These gases are transparent to relatively high-frequency incoming solar radiation in the visible spectrum. However, when this radiation is absorbed on the surface of the Earth it is re-emitted in the infra-red range, which is trapped by the greenhouse gases. This action is similar to the effect of a pane of glass in a greenhouse (or the window of a car sitting in the sun). Without the blanket for the planet that is provided by the greenhouse gases, the Earth would be approximately 30°C colder than it is at present. Carbon dioxide (CO_2) is the most abundant of these heat-trapping gases. Other important greenhouse agents include methane, nitrous oxide, black carbon, and manufactured halocarbons (e.g. chlorofluorocarbons or CFCs).

CO_2 levels in the atmosphere vary over long timescales due to transfers from the atmosphere to the biosphere and the oceans, and from the oceans carbon is eventually sequestered in sedimentary rocks. In the very long term, carbon from the Earth's crust is ejected by volcanic eruptions into the atmosphere, and the cycle begins again.

What has changed in the last 200 years or so is the large-scale emission of CO_2 (and other heat-trapping gases) as a result of human activities, such as clearing of forests and burning of fossil fuels. This process began in pre-industrial times as a relatively minor addition of carbon to the atmosphere but has escalated rapidly in the last 50 years. In 2017, about 37 giga-tonnes (Gt) of CO_2 were released into the atmosphere each year, roughly 150 times more than the amount emitted in the middle of the nineteenth century. CO_2 is a long-lived greenhouse gas: about half of the carbon that is emitted into the atmosphere is taken up by natural sinks within 30 years, but about 30% will persist in the atmosphere for centuries. Nitrous oxide and methane are much more potent heat-trapping gases, but are emitted in lesser quantities. Nitrous oxide remains in the atmosphere for about a hundred years; methane is short-lived, and is mostly removed within about 12 years.

The concentration of CO_2 in the atmosphere rose steadily from about 280 parts per million (ppm) in pre-industrial times, to 315 ppm in 1960 when direct measurements were first made. Since then the level has increased 2–3% per year, reaching a global average concentration of 403 ppm in 2017. Indirect measures, using ice cores and other indications of historic conditions, tell us that present levels are higher than at any time in the last 5 million years (IPCC 2013).

Consequences of these changes in atmospheric chemistry are evident in the recent temperature records at or close to the Earth's surface, sea level rise, reduced snow and ice cover, and increased ocean acidity. The year-to-year variability in average global temperatures is dominated by natural factors such as the El Niño Southern Oscillation (ENSO), so the effect of persistent, external forcing such as steadily rising greenhouse concentrations is seen most clearly on longer timescales. Indeed each of the last three decades has been warmer than all previous decades in the last 150 years and in early 2018 NOAA reported the 5 warmest years on record have occurred in the last 10 years (Climate Central 2018). This rise in global average temperatures has occurred in every region, over both land and ocean, and cannot be explained by time trends in solar activity and other natural forces.

On the other hand, climate simulations that include anthropogenic contributions (i.e. the increase in CO_2 and other greenhouse gases) fit well with the last 40 years of temperature records (Fig. 2.9.1).

Box 2.9.1 Carbon IQ quiz

Indicate which of the following, A to E, is the best answer for each question.

1. If the planet's atmosphere consisted of oxygen and nitrogen, the global average temperature would change by:

   A. −30 degrees C
   B. −10 degrees C
   C. +10 degrees C
   D. +30 degrees C
   E. 0 degrees C

2. Climate is 'average weather'. Over what period?

   A. At least a week
   B. >2 years
   C. >20 years
   D. A century at least
   E. Millennia

3. One-third of the CO_2 emitted today will still be in the atmosphere in:

   A. 1 year
   B. 10 years
   C. 100 years
   D. 1,000 years
   E. 10,000 years

4. Combustion of biomass releases black carbon, other particulates, and aerosols. The effect is to:

   A. Warm
   B. Cool
   C. Affect regional climate, mostly
   D. Accelerate ice melt
   E. All of the above

5. In the last 50 years, what proportion of the warming due to greenhouse emissions has been absorbed by the ocean?

   A. 5%
   B. 80%
   C. 0%
   D. 20%
   E. 100%

6. Up to 2018, the warmest year on record was:

   A. 2010
   B. 1998
   C. 2016
   D. 2017
   E. 1260

7. How many return flights, Singapore to Rome, are required to generate the annual average emissions of CO_2 per capita for Laos?

A. 200
B. 20
C. 1
D. 0.2
E. 0.02

8. If there was a food with the energy intensity of oil, how many litres would be required to cycle 100 km?

A. 200
B. 20
C. 1
D. 0.2
E. 0.02

9. Which US President gave a commitment to translate the UN Framework Convention on Climate Change into ‘concrete action to protect the planet’?

A. George H.W. Bush
B. Bill Clinton
C. George W. Bush
D. Jimmy Carter
E. Richard Nixon

10. Since 1960, the rise in temperatures in the lower atmosphere (the troposphere) has been accompanied by:

A. Stratospheric warming
B. Cooling in the Arctic
C. An overall reduction in precipitation, worldwide
D. Stratospheric cooling
E. Dilution of the oceans making them less acidic

Other evidence of global warming includes the predominance of highest ever temperatures in the record of temperature extremes (in the western United States, record high temperatures now outnumber record low measurements each year by about three to one) (Meehl et al. 2009), and the unique combination of warming in the troposphere (the lower atmosphere) and cooling at higher levels (due to trapping of heat in the greenhouse layer, and less heat radiating into space). Summertime Arctic sea ice is reducing year on year, and global average sea level is rising at about 3.0 mm/year (twice the rate observed before 1990) (Australian Academy of Sciences 2010).

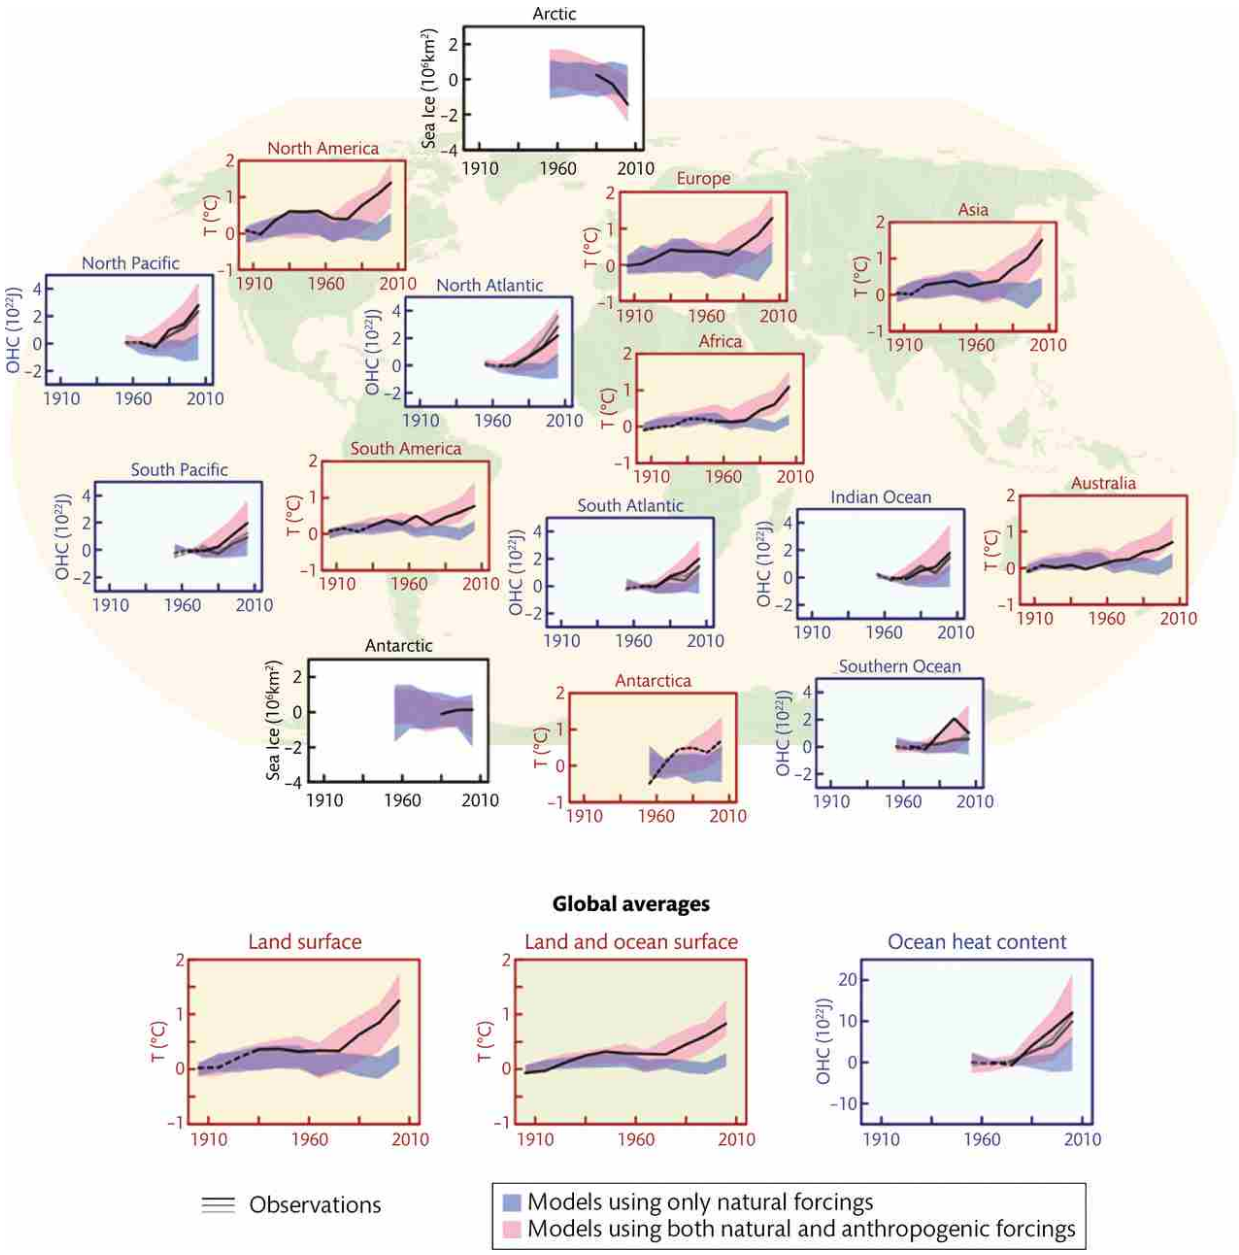

Fig. 2.9.1 Observed and simulated climate change.

Reproduced with permission from Climate Change 2013: The Physical Science Basis. Working Group I Contribution to the Fifth Assessment Report of the Intergovernmental Panel on Climate Change, Figure SPM.6. Cambridge University Press.

Since the 1960s, emissions of greenhouse gases have tracked upwards, the rise halted only briefly by major economic disturbances, such as the Asian financial crisis of the late 1990s (Peters et al. 2011). Emissions in the first 15 years of the twenty-first century have matched, or exceeded, the figures

forecast by the most extreme of the climate scenarios reported in the IPCC's Third Assessment Report in 2001.

What about the future? The 5th Assessment Report of the IPCC forecast that if there was essentially no restriction on the burning of fossil fuels or harmful land use changes (the Representative Concentration Pathway 8.5), atmospheric CO_2 would double pre-industrial levels sometime between 2050 and 2100, and global average temperatures would rise as a result by 3.2–5.4°C relative to 1850–1900 by 2100 (IPCC 2013).

The increase in average temperatures will be accompanied by a marked increase in the frequency of very high temperatures. It has been projected that 'mega-heatwaves' of the kind that caused more than 50,000 excess deaths in Russia in 2010 may increase by a factor of 5–10 in Europe, within the next 40 years (Barriopedro et al. 2011). As average temperatures rise, the incidence of cold events is likely to fall, all else being equal, although there may be unexpected effects in some regions due to feedback loops and critical tipping points. In one example, melting of the Arctic ice has disturbed the high-level jet stream over Europe and North America, re-distributing very cold air masses and leading to the apparently paradoxical phenomenon of warm polar seasons and extreme cold events further south (Liu et al. 2012).

The effects of warming and changes in rainfall will be unevenly distributed, geographically. For instance, a global average of 4°C of warming may be associated with an increase in temperatures in the Arctic of 10°C or more, a decline in rainfall by 40–50% in North Africa, droughts threatening the viability of rain-fed agriculture in many parts of sub-Saharan Africa by the end of the century, and much of south-eastern Australia experiencing extreme fire risks as often as every second summer (4°C and Beyond 2009).

In summary, the greenhouse effect is long known and well described. The rate at which greenhouse gas levels in the atmosphere are increasing is unprecedented, and absolute concentrations are presently higher than at any time since the Pleiocene. In association with these changes, the world is warming, in a manner that carries a discernible human 'fingerprint'. For instance, the mix of carbon isotopes in the atmosphere has changed with the rising contribution of CO_2 from burning of fossil fuels (in which the lighter isotopes especially ^{12}C predominate) (IPCC 2013).

Why is this a public health issue? It is important to recognize that for human health, variability and frequency of extreme events are often more important than average conditions. On exposure to heat or cold, it is deviations from usual or most commonly experienced temperatures that carry the greatest risk.

While humans may be able to cope with modest increases in baseline temperatures, there are physical and ecological systems of importance to health that are exposed to environmental change and may be exquisitely sensitive to temperature rise. Agriculture generally operates as an open system, directly exposed to the weather, with very few buffers against extreme events or long-term shifts in ambient conditions. Warming of 2–4°C in the global average would lead to substantial falls in productivity in some parts of the world. In much of sub-Saharan and southern Africa, it has been projected that an increase of 5°C in the global average would reduce the growing period for some staple crops by more than 20%, threatening the coping capacity and resilience of hundreds of millions of people (Thornton et al. 2011). A small degree of ocean warming above certain threshold limits may lead to death of coral and increased rates of ciguatera (fish poisoning) (Tester et al. 2010). Mosquitoes and other disease vectors also respond acutely to small shifts in temperature and rainfall, and increases in average temperatures will increase the potential for disease transmission in some populations (Wandiga et al. 2010). Conversely, disease risks may be reduced in areas where conditions are presently close to the upper limits of vector survival (Gething et al. 2010). Perhaps as important, historical improvements in health have been built on stable governance, liberty, and relative protection from extreme violence.

Another mechanism by which climate change may affect human health is through conflict, disorder, and displacement of populations. There are many examples in history of social disruption caused by rapid fluctuations in temperature and extremes in precipitation (McMichael 2017). Although the sudden variations in climate in the past resulted from natural causes, such as volcanic eruptions and long-term climate cycles, the consequences resemble what may occur due to anthropogenic climate change. Indeed, the risks may be even higher now, given the scale and speed of change that is projected.

Observational studies of weather, climate, and health

A great deal has been written about variations in weather (day-to-day conditions) and climate (average weather over a period of decades), and their relationship with health outcomes. One of the exposures most closely studied is temperature, which may be expressed in many ways, commonly as the daily average or maximum temperature, with or without an adjustment for humidity. Figure 2.9.2 shows a pattern that is frequently observed—a J-shaped relation between temperature and health outcomes (in this case, mortality excluding accidental deaths). The optimal temperature (the point at which mortality is lowest) differs from one setting to another. In the case of Haerbin, a city located in the far north of China, the number of deaths is at its lowest when the average temperature is close to 0°C (Yang et al. 2007). In cities located closer to the equator, the optimal temperature tends to be higher (Fig. 2.9.2). The overall shape of the curve relating temperature to mortality remains similar, but the point of inflection on the curve moves towards the right in cities where high temperatures are more commonly experienced (McMichael et al. 2008). This is a reminder that populations do adapt to their ecological context, physiologically and socially. What is less clear is how quickly this adaptation can occur, if people move, or the climate changes. Another important question is: what are the limits of adaptation? how much heat is tolerable (Box 2.9.2)?

Box 2.9.2 Too big? Or too big to ignore? The challenge of scale

Climate change is fundamentally different from most other environmental problems that public health has faced. It is a matter of scale. Climate change is a global problem, not only because the effects are widely distributed, like acid rain, or influenza epidemics, but because the underlying cause is a breakdown of Earth's homeostatic systems. Other examples of environmental changes that threaten a 'safe operating space' planet-wide include the depletion of high-level atmospheric ozone by chlorofluorocarbons and loss of biodiversity (Steffen et al. 2015). Climate change moves on prolonged timescales. For instance, the full effects of a spike in greenhouse emissions on warming of the deep ocean and associated sea level rise may not be apparent for 5,000 years or more (Stouffer 2012). This provides a serious challenge to public health scientists. In the last hundred years, with advances in exposure assessment and better knowledge of cellular and molecular mechanisms, the focus has shifted to finer-grained explanations of disease. However the contexts in which chemical reactions occur, microbes multiply, and individuals make their decisions is key to understanding both risk and resilience. For example, mortality in the 1995 Chicago heatwave was a function of both individual-level variables (such as age and income), and the qualities of neighbourhoods. The poor and the elderly were at much greater risk during the heatwave if they lived in areas with rundown businesses, abandoned housing, and degraded public spaces (Klinenberg 2002). Climate change represents a particularly stark example of a big-picture problem, featuring extended timescales, ubiquitous exposures, and the confounding effects of human adaptation. In response, public health

must move upstream, beyond studies of the variations between individuals to investigations of causes on a larger scale (Pearce 2011), and pay greater attention to the ecologic perspective on human disease and injury (Krieger 2015). This will very likely require refinement of established methods of public health inquiry (such as time series analysis, and population-level research designs); an understanding of climate science and meteorology; the creative use of analogues; and the application of relevant modelling methods from other disciplines (e.g. system dynamics modelling) (Rutter et al. 2017).

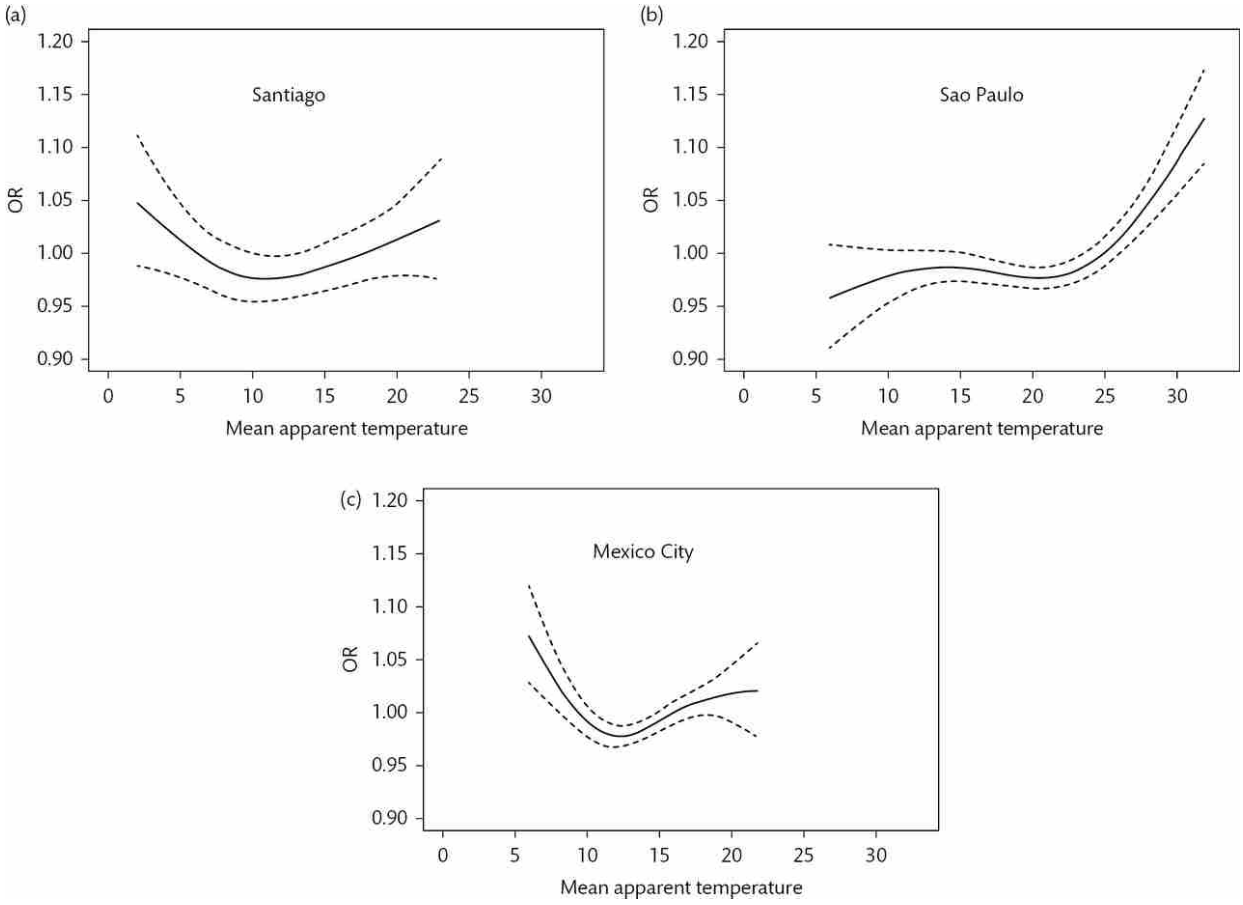

Fig. 2.9.2 Average daily apparent temperature and total mortality: Santiago (33 degrees S), São Paulo (24 degrees S), and Mexico City (19 degrees N). Solid lines show central estimate, dashed lines the 95% confidence intervals. Adjusted for particulate pollution and ozone levels.

Reproduced from Bell ML et al., Vulnerability to heat-related mortality in Latin America: a case-crossover study in São Paulo, Brazil, Santiago, Chile and Mexico City, Mexico, *International Journal of Epidemiology*, Volume 37, Issue 4, pp. 796–804, Copyright © The Author 2008, with permission from Oxford University Press.

Higher temperatures have been linked with a range of health outcomes including deaths and hospital admissions for respiratory and cardiovascular

diseases. In heatwaves, which may be defined as prolonged exposure to temperatures in the top 5–10% of the range for that location, the effects appear to be greater than would be expected by simply extrapolating the temperature–health outcome relationship (Anderson and Bell 2011; Rocklöv et al. 2012). Duration of heat, frequency of heatwaves, and timing (early or late in the season) all appear to modify the effects of high temperatures. High levels of air pollution amplify the damaging effects of heat (Qin et al. 2017).

There is considerable variation within populations in vulnerability to heat. Older people (70 years and over) and children are generally at greater risk. There is no consistent pattern with gender. Men were found to be at greater risk in São Paulo and Santiago (Bell et al. 2008); whereas a study in Brisbane, Australia reported a more marked increase in mortality risk for women than men (Huang et al. 2012). In many countries, low socioeconomic status (SES) has been associated with increased risk of heat- and cold-related poor health (Qin et al. 2017), but again, this is not universal. There is, for example a greater variation by SES in heat mortality in the United States than in England, perhaps because the use of air conditioning is distributed differentially in the United States but not so much in the United Kingdom (where few houses have artificial cooling and there is much less social variation) (Armstrong et al. 2011). Vulnerability is also expressed spatially (Uejio et al. 2011) reflecting the geographical distribution of individual and household characteristics (such as prevalence of chronic diseases, housing design, and poverty) and also district-level variables (urban form, quality of services).

It is not just the maximum or average temperatures that affect health. Variability is important as well. In 135 United States cities, for example, the standard deviation of summer temperatures was associated with mortality of older people suffering from chronic disease, after adjustment for a wide range of risk factors including average temperature (Zanobetti et al. 2012).

As with many climate change impacts, more is known about the effects of high temperatures in high-income countries than in the developing world, although the problem is likely to be more severe in the latter, given the high temperatures that already apply in many low-latitude countries, the very large populations, often with multiple health problems, that are exposed, the large number of outdoor workers and the low quality of housing and urban environments.

The effects of heat on the health of workers has emerged as an important issue, given the large number of people who may be affected, and the multiple adverse consequences of reduced productivity and loss of livelihoods (Lucas et al. 2014). This is especially significant in equatorial countries where high temperatures already place severe restraints on the duration and intensity of outdoor work (Kjellstrom et al. 2013).

The effects of climate on infectious disease have long been known (see Box 2.9.3). The first textbook of tropical medicine, by Patrick Manson, was published in 1900, and was called *A Manual of the Diseases of Warm Climates* (Manson 1900). Manson wrote principally of infectious diseases but he recognized that few conditions were peculiar to the tropics. In other words, he understood that climate variables such as temperature and precipitation play an important part in, but are seldom the entire explanation for, the distribution and occurrence of disease.

The mosquito-borne diseases are good examples. In warmer conditions, vectors such as *Aedes aegypti* (responsible most commonly for the transmission of dengue fever) develop more quickly from the immature stage (Tun-Lin et al. 2000). In tropical countries in which temperatures vary little through the year, the transition from a time of low rainfall to the rainy season may act as a powerful climatic trigger for outbreaks of dengue (Schreiber 2001). But other factors are important also. Urbanization and the quality of housing, for instance, modify the effect of climate on dengue risk (Wu et al. 2009). Overall, it is projected that climate change will extend the present geographic range of dengue and threaten populations which do not currently experience local transmission of the disease (Ebi and Nealon 2016).

Box 2.9.3 Plague and climate

Plague is caused by infection of humans with *Yersinia pestis*. The organism is established in rodent populations in parts of Asia, Africa, and the Americas, and periodically causes outbreaks of disease in local populations. The prevalence of *Yersinia* in animal hosts is climate sensitive. For example, a study of gerbils in Kazakhstan found the risk of disease was increased by warmer springs and wetter summers (Stenseth et al. 2006). An increase of 1°C in spring was associated with an increase of more than 50% in the prevalence of animals infected with *Yersinia*. Climate also affects the abundance of rodent hosts and flea vectors, as well as the chances of humans coming into contact with the pathogen. Consequently, it is not surprising that many historical studies have shown a link between climate and plague epidemics (McMichael 2017). As one example: a study of plague in China between 1850 and 1960 found the number of cases per year was positively related to rainfall,

although extremely high precipitation in the wetter parts of the country led to lower than expected plague intensity (Xu et al. 2011).

There are many ways by which physical and mental health may be affected by variations in climate or weather. In the south-western part of Australia, the prevalence of depression has been related to the severity of long-term drought (measured as dry-land salinity) (Speldewinde et al. 2009). The physical degradation of environments following climate change has been linked to loss, grief, separation, and self-questioning in many environments (Berry et al. 2010; Cunsolo and Ellis 2018). Non-communicable diseases may be affected: in Bangladesh the dry season is marked by increasing salinity and rising temperatures of the ground water, and it is thought these changes are linked to marked seasonal variations in the incidence of high blood pressure and eclampsia in pregnancy (precipitated by increases in sodium loading) (Xun et al. 2010). Cholera is another marker in Bangladesh of warming and salt intrusion, but indeed all the vibrio pathogens (including *vulnificus* and *parahaemolyticus* as well as *cholerae*) are temperature sensitive and have been described as 'microbial barometers of climate change' (Baker-Austin et al. 2017).

In summary, humans have adapted to local conditions during a period of relatively stable climate (the Holocene epoch),but are susceptible to ill-health caused by rapid changes in temperature and precipitation. The connection between extremes of cold and heat on mortality is well established, and many infectious diseases also vary with climate.

Attribution—present impacts of climate change

In 2013 the Fifth Assessment Report of the IPCC concluded that 'It is extremely likely more than half of the observed increase in global average surface temperature from 1951 to 2010 was caused by the anthropogenic increase in greenhouse gas concentrations and other anthropogenic forcings' (IPCC 2013, p. 17). In the IPCC lexicon, 'extremely likely' means the probability is more than 95%.

The IPCC assessment reports have described many changes in physical and biological systems that are consistent with global warming. For example, during the last one hundred years the distribution of North Sea cod has changed dramatically, with fish moving northwards and into deeper

waters, largely as a consequence of ocean warming (the other influence being the pressure of commercial fishing) (Engelhard et al. 2014). In the Alsace region of France, in association with higher summer temperatures, the potential alcohol content of Riesling grapes, at harvest, increased by almost 1% per year (Duchêne and Schneider 2005). It is not difficult to attribute changes such as these to climate change, as there are few alternative plausible explanations.

The story of tick-borne diseases, including Lyme disease and tick-borne encephalitis (TBE) illustrates well the complexities of attribution. In the last decade of the twentieth century the vector for TBE moved northward across the Baltic and Scandinavia, in association with warming that has been most marked in winter and early spring (Lindgren and Gustafson 2001). The incidence of TBE surged in the early 1990s in the Baltic states, but this did not fit closely with climate. There were considerable variations within the Baltic in TBE rates, and although warming continued after 2000, TBE rates fell (Sumilo et al. 2007). Clearly there are other factors that are important besides the arrival of a climate that was more favourable for transmission of the TBE virus. When the Soviet Union broke up in 1989, many collective farms ceased to operate, areas that had been used for pasture and agriculture were left untended, and these provided new habitat for rodents and deer. At the same time, during a period of economic disruption and transition, people were more dependent than before on wild food sources, including mushrooms and small game, and as a result spent more time in the countryside. In combination these changes, climatic and non-climatic, may have increased tick abundance and boosted, for a short time, the exposure of humans to tick-borne diseases (Sumilo et al. 2007).

Lyme disease emerged in the United States in the 1970s, most likely due to socioeconomic changes and transition of farmland in the north-east to forests (Ebi et al. 2017). The disease was slow to get established in Canada, although the local habitat was suitable and there was movement of natural hosts, vector, and pathogen (*Borrelia burgdorferi*) across the border from the United States. It is likely that temperature was the limiting factor. Since 2000, in the same period as lower Canada has warmed, local populations of the tick vector have established, and the number of cases of Lyme disease has increased. The links between environmental change, the shift of vectors, and the onset of disease suggest that the spread of Lyme disease, in this region, is due in part to climate change (Ebi et al. 2017).

In public health, attribution involves probabilities, based on the risk of an event occurring following a particular exposure, compared with the probability of the same event taking place without the exposure. The inability to attribute a particular instance of lung cancer to cigarette smoking is quite consistent with a firm conviction that smoking causes the majority of such cancers in populations in which tobacco use is common. Such an approach is applied also in climate sciences to make judgements about the causes of extreme events. For instance, a study of cyclones in the north Pacific in 2015 concluded the extreme energy levels that were observed were highly likely to be due to human-induced climate change (Woodward and Samet 2018). A study of the 2003 European heatwave concluded it was very likely (probability greater than 90%) that human influences on climate had more than doubled the risk of such an extreme event (Stott et al. 2004). Note that a relative risk of more than 2.0 means it is more likely than not that the outcome is attributable to the exposure.

Forecasting

To attribute past and present morbidity and mortality to climate change is not straightforward, but future attribution presents even greater difficulties. There is no certainty about how much the climate will change in the future, or what the consequences will be, but it is clear that the most important risks lie ahead of us. Present-day effects of climate change on health may be miniature versions of future effects, or perhaps not: future challenges may be threshold-crossing novelties. For this reason, a great deal of effort has been applied to attempts to project future climates and the consequent impacts through modelling studies. One approach is to attempt to isolate the effect of an altered climate on specific diseases by holding all other independent variables constant. We will look at examples of this approach using several diseases known to be highly climate sensitive. Since climate change acts as a multiplier of disadvantage, ideally studies would go further and ask: how are the ‘baseline’ risks likely to change in the short to medium term? This is a difficult undertaking but could, potentially, provide a more accurate description of future impacts of climate change on human health. Modelling studies that have taken this approach are less common and require methods not so familiar to epidemiologists—methods that can deal with significant

levels of complexity, non-linear interactions, and feedback dynamically over time.

A study of future impacts of climate change on the 'potential transmission' of malaria in Zimbabwe attempted to isolate the effects of climate between 2000 and 2050, by assuming there would be no other changes (Ebi et al. 2005). The suitability of the climate for stable transmission of *Plasmodium falciparum* malaria was related to mean temperatures, winter minimum temperatures, and monthly rainfall, based on outputs from the MARA (Mapping Malaria Risk in Africa) project. On this basis the researchers reported that within 50 years malaria could be established in the densely populated and presently malaria-free highlands of Zimbabwe. The model used in this study was risk based (suitability varied from 0 to 1), was explicitly projecting the potential for disease, rather than predictions of disease occurrence, and set aside the question of how other influences on malaria, apart from climate, might differ in 2050 from the present day.

In a less common non-communicable disease example, a study in the United States modelled the current relation between mean annual temperature and hospital admissions for stones in the urinary tract in the United States. In general, nephrolithiasis is more common in populations living in warm climates, and this trend is apparent in the United States. The authors applied projections of mean annual temperatures in the future and calculated the potential increase in hospital admissions and associated costs (Brikowski et al. 2008). Since both linear and non-linear relationships between temperature and risk fitted the present data, both forms were modelled. Projections were based on one of the IPCC's intermediate severity climate change scenarios (SRES A1B).

Even more challenging is to model the future burden of disease due to climate change impacts on the upstream determinants of health. Crucially, the effects of climate change on the global food system may have far-reaching effects on health. To investigate this issue, researchers linked models that projected food supply under different climate scenarios with estimates of the effects of changes in fruit and vegetable consumption, red meat intake and bodyweight (Springmann et al. 2016) (Fig. 2.9.3). The study was the first to assess the effects of changes in diet composition (e.g. intake of fruit and vegetables), and found that this was more important in terms of health outcomes than simple loss of calories. It was assumed that recent

improvements in most parts of the world in food security and nutrition-related health outcomes would continue, so the main effect of climate change would be to act as a brake on progress. Limitations in this assessment include the relatively short time-frame (up to 2050 only), inability in a global assessment to accurately capture local conditions and the particular difficulties faced by some populations (e.g. those on low-lying Pacific islands), and the possibility that wide-ranging mitigation policies might themselves threaten the production and distribution of food (Woodward and Porter 2016).

Reproduced from Springmann et al. (2016) 'Global and regional health effects of future food production under climate change: a modelling study', *Lancet*, with permission from Elsevier.

Demographic projections are important, since climate change impacts will depend on the size, structure, and health status of world populations. The mid-range estimate is for the world population to increase from about 7.6 billion presently to around 9.7 billion by 2050, with most of the growth occurring in developing countries (United Nations 2015b). The proportion of the population in older age groups is likely to increase, almost everywhere, although the average years of life remaining will change much less (Lutz et al. 2008). Mortality is projected to decline, in most countries, leading to increases in life expectancy at birth of around 5–6 years by the mid-century

(World Health Organization 2011). Assuming that present trends of social and economic development continue, illness rates will also decline, and it has been estimated that the overall burden of disease (measured in disability-adjusted life years) will be reduced by about 30% by 2030 (World Health Organization 2008). Child mortality is falling, worldwide, with no sign of a reduction in the rate of improvement (You et al. 2015). However, there are still very large differences between countries, and some, especially in sub-Saharan Africa, are improving slowly, if at all (World Health Organization 2011).

How could it be that health statistics are improving around the world while pressures mount on the global environment, from climate change and other big-picture problems (e.g. loss of biodiversity, overloading waterways and soils with nitrogen and phosphorus)? We have no clear reference point of course: mortality may have fallen more rapidly, child stunting may have diminished sooner, if climate change was not acting. But the more important point relates to timing. There is good reason to believe the full costs of large-scale human exploitation of the planet have not yet become apparent (McMichael 2017): human populations have been ‘eating the future’ by headlong clearing of land, burning of fossil fuels, and drawing down on sources of fresh water.

Whether social and economic development continues on the present trajectories is of course unknown, but is fundamental to projections both of climate change and vulnerability to its effects. In turn, uncertainty about the pace of social and economic development stems, in part, from the possible effects of climate change on societies and economies, and on the pathways we take in responding. Furthermore, health is sensitive to the manner in which economic growth occurs. If development is not inclusive, then vulnerability to the effects of climate change may not improve. India, for instance, has taken great strides, economically, in the last 20 years, but the health problems of poverty persist for many people. The prevalence of child underweight and stunting fell modestly between 1992 and 2005 (from 49% to 40% underweight, for instance), but there was no relation, at the state level, with income growth (Subramanyam et al. 2011). Child health measured in this way advanced no faster in the richest states than the poorest.

These examples demonstrate the intertwined nature of climate change and development and serve as an entry point to understanding that climate

change and our actions to address it are issues of social and environmental justice, equity, and human rights. The highest income countries have achieved substantial improvements in life expectancy, health, and quality of life, in significant part due to fossil-fuel dependent economic development. Up to 2010, the most developed countries had contributed more than half of all anthropogenic emissions, despite being home to only 17% of the global population (den Elzen et al. 2013). On the other hand, we have already demonstrated that the impacts of climate change are being, and will continue to be borne, by the lowest income countries and populations within countries who are already experiencing socioeconomic inequities. The relationship between climate change and human rights is discussed further in Chapter 2.9. Indigenous peoples are both particularly vulnerable to the health impacts of climate change and have specific resilience capabilities and knowledges for mitigation and adaptation (Ford 2012). These are discussed in detail in Chapter 10.6.

Will there be positive effects of climate change, and if so, how will they balance the negative impacts? This is not a straightforward question to answer. It is likely there will be some positive effects in the short term, but it is difficult to judge their magnitude. For instance, it is likely that modest warming will boost agricultural yields in temperate parts of the world, increasing food production in these regions. Moreover, food crops such as wheat, rice, barley, and oats, tend to grow more quickly in higher levels of CO_2. Together, these effects may reduce the risk of food shortages and undernutrition caused by lower production in hot, low-latitude countries (Gornall et al. 2010). The balance of gains and losses will depend on whether populations at risk of food shortages can in fact get access to the climate dividend, and the relief may be temporary: the increase in crop yields in temperate zones will almost certainly diminish as warming continues (Teixeira et al. 2011). In tropical developing countries, where food insecurity is greatest, the impact will be most severe. In sub-Saharan Africa, where the caloric intake of 60% of the population in the late 2000s was insufficient for an active life, 5 degrees of warming (global average) is projected to cut maize yields by 19% and beans by 68% (Thornton et al. 2011).

Where disease vectors and pathogens are already close to the upper temperature limit for reproduction and transmission, further warming is likely to reduce the risk of disease. In parts of equatorial Africa, for example,

projected temperatures will exceed the optimal settings for both the vector and the parasite, and the potential for malaria transmission will rapidly diminish (Ebi et al. 2017).

The effects of cold and heat on mortality have been closely studied, and shed some light on the matter of balancing gains and losses with global warming (Ebi and Mills 2013). The J-shaped relation between ambient temperature and mortality suggests that warming will lead to fewer cold-related deaths, and greater heat-related mortality. This curve is rarely symmetrical—in cooler locations, the right-hand arm of the curve (associated with heat) tends to rise more rapidly, and the opposite is true for populations living in relatively warm conditions. This means that if there is a trade-off of gains and losses with warming, the balance will depend on the initial conditions. But it is more complicated still—it is not clear whether cool-location populations will retain their (relatively greater) tolerance for cold as temperatures rise, or whether the shape of the temperature–mortality curve will change. Also, it is uncertain how many of the deaths that occur at colder times of the year are in fact due to low temperatures, rather than other phenomena that vary with season (such as infectious disease epidemics). Many populations in colder parts of the world, where the most affluent and best buffered populations in the world are located, have adapted to a large extent to cold, and the impacts of both cold spells and ambient low temperatures have much reduced over time. Consequently, the added benefits of global warming in these locations may be modest, and outweighed by the additional burden of heat-related ill-health in the much larger and more vulnerable populations living in low latitudes (Kinney et al. 2015).

It is important to identify the most important sources of uncertainty in projections. A study of diarrhoeal disease attempted to distinguish the effects of uncertainties in temperature changes and the exposure–response function (change in disease incidence per unit warming) (Kolstad and Johansson 2011). The focus in future-oriented studies tends to be on the climate modelling, given the many assumptions that have to be incorporated. However in this case it was evident that uncertainty associated with the risk coefficient (which varied almost fourfold between studies) caused more variation in the outcome than the choice of climate change model. Another study in the United States examined the effects of modelling choices on national mortality attributable to low-level ozone, in the presence of climate

change (Post et al. 2012). Results varied from about 600 deaths per year avoided as a result of climate change to 2,500 deaths attributable to climate change (although most models projected increases in mortality). The most influential analytic steps were the choices of climate change scenario and air quality model. It should be noted also that the ozone studies, and many other investigations of climate impacts, have tended to project effects based on mid-range climate scenarios, when the globe is in fact tracking on a steeper trajectory for emissions, one that fits more closely with the high-range models. This highlights the issue of thresholds and tipping points—as we move further away from familiar environments and encounter more extreme exposures, it becomes less certain that present exposure–response relations will apply in the future.

There are two ways of responding to climate change: adapt to the new environment (analogous to secondary prevention) and mitigate (primary prevention—take whatever steps are needed to avoid further, increasingly dangerous climate change occurring). Primary prevention is necessary from a public health perspective, but there are strong imperatives for now also investing in adaptation: in particular, the world is committed to warming as a result of greenhouse gases already emitted, due to the long time-course of global carbon cycles and heat transfers. This is regardless of future emission trajectories. Both adaptation and mitigation have implications for health, and we deal with each in turn.

Adaptation to expected climate change

The importance of adaptation is proportional to the extent and momentum of climate change—when there are very long lag times in the climate system then interventions to reduce emissions will take a very long time to have their full effect, and in the meantime, steps must be taken to cope with changes that are, in effect, unavoidable. The IPCC's Fifth Assessment Report estimated the Earth has already warmed by 0.85°C on average, compared with the late 1800s, with a resulting decrease in cold days and nights, a likely increase in both heat waves and heavy rainfall events (particularly in North America and Europe), and sea level rise of about 20 cm (IPCC 2013). It has been estimated that we are already committed to further warming of at least 0.7°C over the next 30 years because of the greenhouses gases that are now in the atmosphere. Also in the atmosphere

are airborne pollutants, many of which have a cooling effect, and are tending to dampen down the global warming signal. It is difficult to determine the size of this effect, but it may be as much as 0.2°C of latent warming that will be expressed when local air pollution is better controlled and fossil fuel use declines (IPCC 2013).

Then there is the question of future emissions. In 2015, the United Nations adopted the Paris Agreement, since signed by all member states and ratified by 175 of 197 members, including the United States and China (the two single largest emitting countries, responsible for 45% of global emissions). The Agreement commits parties to increasing cuts to emissions to keep average global warming to below 2°C (the globally agreed threshold for 'dangerous' climate change), while aiming for no more than 1.5 degrees to protect the most vulnerable low-lying island states from devastating sea level rise. While not legally binding, the Paris Agreement is the first truly global instrument to address climate change, and recognizes both the need to protect health, and the opportunity for health co-benefits in well-designed climate action (United Nations 2015a). At present, global emissions are close to 50 Gt CO_2 equivalent per year, about 14% higher than the level required to hold warming to around 2°C. Following decades of rapid growth, the years 2014–2016 saw global emissions plateau for 3 years but in 2017 emissions rose again, to an historic high. This resulted from increasing energy demand and a slowdown in energy efficiency improvements (International Energy Agency 2018). There is a mixed picture emerging internationally. Some countries (including the United States and members of the European Union) are tracking steadily downwards, while emissions continue to rise in large, rapidly-developing countries such as China. The year of peak global emissions is critical. The sooner greenhouse emissions worldwide begin to fall the less painful the pathway to climate targets. For example, if global emissions did not peak until 2025 and then reduced by 3% per year, global average surface temperatures would rise by as much as 4 degrees C by the end of this century. More severe reductions, about 8% per year, would be needed to stay within 2°C (Hausfather and Pearce 2017).

On the one hand, there are strong forces driving emissions upwards. These include population pressures (a 50% increase projected worldwide in the next 50 years) and economic development 'catch up': 90% of the growth in emissions this century will come from states that are presently in the low- and middle-income categories. On the other hand, there is some evidence

that economic development and emissions are beginning to 'decouple', especially in South America (Hausfather and Pearce 2017). Further, there is increasing global political leadership from many of the high-income countries responsible for the majority of emissions, as evidenced by the Paris Agreement. Even in countries where there is a lapse of national-level leadership (such as the US president's threats to leave the Paris Agreement), local and state-level governance continue to be committed to reducing emissions in line with obligations. There are also some helpful feedbacks at play. For example, as alternatives to fossil fuel energy generation such as solar panels and wind turbines become more popular, the price of these alternatives fall, making them even more attractive. Both onshore wind and photovoltaic solar generation now have cheaper lifecycle costs than the marginal cost of continuing to generate electricity by burning coal in existing power plants (International Renewable Energy Agency 2018).

Locked-in climate change and the risk of mitigation failure are both compelling reasons to find options for coping with climate change impacts, particularly adaptation to increasing average and extreme temperatures, as well as resilience to storms, flooding, sea level rise, and disruption to agricultural production and distribution. Here we will examine some of the opportunities for adaptation, ranging from individual behaviours to neighbourhood interventions, to sector-wide changes. Some of the available options for adapting to climate change can also assist with climate change mitigation, or have other co-benefits for health and equity, while others may hamper efforts in these areas. We cover some examples relating to heat and storm events.

At an individual level, improving the body's physiological response to temperature extremes can assist with adaptation. Increasing physical activity, reducing obesity, and improving diabetes control have many benefits to health, including enhanced capacity to deal with heat (Kenny and Jay 2013). Clinical trials have shown that short-term endurance training increases sweat rate and peripheral blood flow and leads to more effective control of body temperature during exercise (Ichinose et al. 2009). Overweight military recruits in the United States were found to be seven times more likely to suffer heat illnesses during training than their colleagues (Bedno et al. 2010). Work of this kind indicates that public health programmes to promote physical activity, prevent unhealthy weight gain, and reduce the prevalence of obesity are likely to reduce vulnerability to heat.

Community-oriented interventions have promise, since risk factors for heat-attributable deaths tend to cluster spatially. For instance, studies in New York City found that poverty, ethnicity, poor housing, exposure to greenspace, and the prevalence of hypertension were all associated with heat wave mortality, and vulnerable census tracts may be identified through a comprehensive neighbourhood heat vulnerability index (Madrigano et al. 2015).

Although air conditioning has been advocated by some as an important measure for coping with high temperatures (Ostro et al. 2010), it brings vulnerability, as well as consuming large amounts of (often fossil fuel-based) electricity, and transferring further heat outdoors. Artificial cooling relies on a consistent power supply, and heatwaves may trigger electricity outages due to air conditioning demand overload (Anderson and Bell 2011). In these circumstances, populations accustomed to living with air conditioning may be at increased risk of ill-health due to high temperatures. Buildings designed for air conditioning are often poorly designed in other ways to deal with heat (with large, exposed surfaces of glass, and minimal natural shade, for instance). Also, physiological adaptation requires some exposure to heat strain, that is, an increase in body temperature (Maloney and Forbes 2011). Populations with around-the-clock access to air conditioning are less likely to develop the capacity to respond to extreme temperatures, when and if this occurs. Since most deaths during heat waves occur inside buildings, a focus on passive building and surrounding measures that don't rely on energy use will be vital for equitable heat wave survival ('passive survivability') (Baniassadi and Sailor 2018). These include window design, balancing insulation for cold and heat, and balancing tensions between well-designed ventilation and shading, and energy efficiency through all seasons.

Cities are significantly warmer than their surrounding rural areas (the urban heat island effect) due to darkly paved surfaces and dense anthropogenic heat generation (e.g. from vehicles and buildings). City-level interventions to reduce the health risks due to high temperatures will therefore be important (Phelan et al. 2015). Designing cities to reduce the heat island effect can also make them safer during times of high temperature. A study in Phoenix, Arizona estimated the reduction that could be made in heat-related emergency calls by an urban re-design package (Silva et al. 2010). This included changes in building and road materials to increase heat flows, more urban green spaces, rooftop treatments, and widespread

application of reflective paints. In combination, the authors estimate, these interventions could reduce inner-city temperatures sufficiently to almost halve the number of annual heat-related emergency calls.

Measures at a city-level to manage high temperatures when they do occur include heat-health early warning systems, better cooling of at-risk environments (such as residential care facilities for the elderly), identifying the isolated and most vulnerable citizens, and improving the preparedness of the healthcare sector. In France, many such changes to heatwave responsiveness were made following the severe heatwave in 2003. When another heatwave occurred in July 2006, the question asked was: did the country cope better this time than it did in 2003? In July 2003, the increase in daily temperatures was theoretically sufficient to increase daily mortality by about 230%, according to the long-run (1975–1999) relationship between temperatures and daily deaths (Fouillet et al. 2008). But a 290% increase was observed, an excess of more than 15,000 deaths. In 2006, the heatwave temperatures were not as high as 3 years earlier, and it was theoretically projected to raise mortality by about 60%. In fact, the death rate increased by only 14%. One possible explanation is that the 2003 disaster brought forward many deaths in relatively frail individuals, greatly reducing the pool of susceptibles in 2006. However, the mortality trends indicate the 4,600 fewer-than-expected deaths in July 2006 were indeed evidence of more effective adaptation.

The contrast between more aggressive air conditioning and greater provision of green space in cities is an example of how ‘business as usual’ approaches can miss important opportunities (Hess et al. 2012). On the one hand, enhancing air conditioning helps to protect some of the most vulnerable individuals from high temperatures, though it carries a heavy cost in power consumption. On the other hand, a radical expansion in urban green spaces and street trees may bring a range of benefits (in addition to cooling), including carbon sequestration and health benefits due to reduced air pollution, better mental health, and more opportunities for physical activity (Salmond et al. 2016). But these ‘win-win’ interventions are seldom straightforward: green spaces on their own may not be sufficient to achieve health gains. A study of the 49 largest cities in the United States (Richardson et al. 2012) compared the extent of green space with all-cause mortality, adjusting for important social and demographic differences, but not for measures of urban density. They found, against expectations, that health

appeared to be worse in greener cities, and this was explained by the negative effects of factors associated in the United States with green suburbs, mainly sprawling land use and high car dependence.

Another important area for adaptation is in preparedness and resilience to severe storms and flooding. Most climate change models project an increase in the intensity of tropical storms, though it is less clear whether the frequency of storms will change. These extreme events already cause substantial loss of life and economic damage. For example, in Burma in 2008, Cyclone Nargis caused approximately 138,000 deaths and US $10 billion damage (Fritz et al. 2009); in the United States, Hurricane Katrina in 2005 was responsible for about 1,200 deaths (Blake and Gibney 2011) and direct losses of over US $130 billion (Field et al. 2012). Yet, in almost all regions more recent storms of similar or greater severity have seen lower event mortality rates, despite increasing populations living in vulnerable coastal zones globally. Southeast Asia is an important exception to this, due to frequent cyclones, very dense coastal cities and variable preparation and warning systems (Bouwer and Jonkman 2018). There are examples of countries with an improved record for managing the health risks of storms and cyclones. Cuba was struck by four destructive hurricanes (category 2 or greater) between 1998 and 2002. While tens of thousands of homes were damaged and hundreds of thousands of people were evacuated, there were very few deaths (12 in all) (Thompson and Gaviria 2004). While Hurricane Katrina killed many in the United States, no deaths resulted in Cuba from the same storm, despite 20,000 homes being destroyed. The large number of deaths associated with Hurricane Katrina in the United States was a result of serious deficiencies in the public health system, and lack of protection for the poorest and most marginalized social groups in the city (Brunkard et al. 2008).

In contrast, Cuba invests heavily in traditional civil defence activities, including stockpiles of equipment, clothing, fuel, and food. There are effective storm warning systems, and good means of communicating information to the public. Other factors that contribute to resilience are high levels of literacy, provision of basic facilities in all rural areas, and a comprehensive and accessible primary healthcare system. An Oxfam analysis of disaster preparedness in Cuba found there was strong community engagement, so that populations that are threatened can be mobilized rapidly, and protection extends to all social groups, not just those with personal

resources (Thompson and Gaviria 2004). These more immediate disaster preparedness activities are complemented by longer term shifts in the built environment, involving housing construction, land use, and urban planning (Lizarralde et al. 2015). The Cuban example is salutary for climate change adaptation for public health. Building resilience to protect health from climate change will require co-ordinated actions by central and local government, health, and other sectors, as well as communities.

Table 2.9.1 The five main pillars of disaster resilience in Cuba's built environment

Pillar	Scale	Stages of intervention	Types of intervention
Construction industry development	Country	Prevention, reconstruction, long-term development	Project[a], programme[b], national policy
Housing development	Country	Prevention, rehabilitation, reconstruction, long-development	Project, programme, national policy
Systematic urban and regional planning	Community, city, region	Prevention, reconstruction, long-term development	Plan[c], urban policy
Early warning systems	Country	Prevention, emergency	National policy and campaigns
Evacuation plans	Individual, community	Prevention, emergency	National policy and campaigns

Notes:

[a] Often undertaken by one institution with specific objectives and timeframes.

[b] Often undertaken by one institution over a long period of time.

[c] Involves more than one institution and is revised or updated periodically.

Source: data from Lizarralde, G., Valladares, A., Olivera, A., Bornstein, L., Gould, K., & Barenstein, J. D. (2015). A systems approach to resilience in the built environment: the case of Cuba. *Disasters, 39*(s1), s76–s95. doi: 10.1111/disa.12109

There are other opportunities to learn from the variability in past experience of coping with climate-related health problems. For instance, enteric infections such as that caused by *Salmonella* tend to be more

common at higher temperatures, but the size of the increase in disease rates for a given amount of warming varies from one site to another. A study of the five largest Australian cities found that all showed an increase in *Salmonella* notifications with monthly mean temperature, but one city stood out as following a much steeper trajectory than the others (D'souza et al. 2004). Perhaps aspects of the food safety programmes present elsewhere are missing in this apparently particularly temperature-sensitive city.

There is no doubt that climate change acts principally as a risk multiplier. The greatest impact will occur in populations that, for other reasons, already have the worst health statistics, while patterns of economic development now also shape future climate change vulnerability. The World Bank in its landmark 2010 report on climate change and development concluded that 'baseline health status is the single most important determinant of both future losses, and the cost of adaptation' (World Bank 2009). It follows that adaptation must include improvements in the social determinants of health, including social safety nets, as well as essential public health services. But is it true that this is all that is needed? In other words, is 'business as usual' development, the package of improvements that we would want to be making anyway, sufficient preparation for climate change?

Together with leading economists (Fankhauser and Stern 2016), we argue that 'business as usual' patterns of economic development will not be sufficient. Climate change is unique in geographic scale, long time lags, and momentum. Impacts accumulate and progress with such long lag times (sea level rise is a good example) that the process must be regarded as irreversible over our usual public health timescales. This is not a one-off event, but a new environmental dynamic, with enormous momentum. We are likely to be pushed to the edge of what is familiar, and beyond, leading potentially to abrupt and radical changes in Earth systems (Lenton and Ciscar 2013). In epidemiological terms, even if the trends in exposures (rising temperatures, changing patterns of precipitation) remain the same, it may be difficult to anticipate the dose–response relationships that apply in the future, due to unforeseen tipping points, thresholds, and non-linearities. The much greater than expected damage caused by unprecedentedly intense bushfires in Victoria, Australia in 2009 is a good example (Teague et al. 2010).

Climate change does not *only* multiply existing risks. It may contribute to new risks where ecosystems are pressed beyond significant thresholds. This

may happen on the edges of areas affected by climate-sensitive diseases. One example is the acute illness that occurs after eating sea-foods contaminated with *Vibrio parahemolyticus*. The organism is temperature sensitive, and until 2004 no instances of this particular food poisoning had been reported in North America above the US/Canada border. In that year there was an outbreak of cases on a cruise ship in Alaska, linked to shell-fish from a local oyster farm in Prince William Sound. On investigation, it was found that water temperatures at the farm (and the surrounding ocean) had been rising steadily for a decade, and presumably had crossed a critical boundary beyond which the organism could be sustained in local shell-fish (McLaughlin et al. 2005).

Altogether, these unique aspects of climate change require special responses to meet health in development goals. In particular, agricultural investments and rapid urban infrastructure development will need to simultaneously be resilient to climate change impacts, low-carbon, and health-promoting, requiring unprecedented partnerships across sectors—signalled by SDG 17.

Finally, it is crucial to note the limits to adaptation (Dow et al. 2013), emphasizing the need to address the root cause of climate change (anthropogenic greenhouse gas emissions). These limits include human physiological tolerance to extreme heat; limits to the geographical and physiological adaptation of other species on which we rely (such as food plants and pollinators); financial limits to disaster protection, response and recovery; and socio-political limits to governance under multiple stressors, leading to conflict and mass migration.

In summary, given the extent of committed warming, and the difficulty of achieving substantial reductions in emissions, the world almost certainly faces large changes in the next half century. Improving baseline health status is fundamental to adaptation, but not sufficient—there are distinctive features of climate change that have to be taken into account. Discussions about adaptation also help us to understand the limits to adaptation and the importance of urgent action to reduce the future extent of climate change (Evans et al. 2014) (Box 2.9.4).

Box 2.9.4 Health sector action on climate change

The health sector itself will need to take both adaptation and mitigation actions in direct response to climate change, over and above the general strengthening of public health activities and improving access to healthcare. In addition, the sector will need to adapt to the necessary reduction in the availability, and increase in price, of fossil fuels (and oil-based products such as plastics) that must occur in order to reduce greenhouse emissions substantially.

Adaptation actions will need to be shaped locally or regionally to respond to contextual variations in climate-related disease risk, available resources, and uncertainty (Confalonieri et al. 2015). For example, the US Resilient Hospital Dashboard (Four Twenty Seven 2016) uses localized climate and healthcare data to inform adaptation and resilience decisions.

However, some generalizable areas for consideration have been recently described in the World Bank's 2017 report on Climate Smart Healthcare. These encompass infrastructure, material resources, and supply chains, workforce planning, and resource allocation to particular services.

Decisions on location and design of new hospitals and healthcare facilities must incorporate local information about climate impacts, including flood risk, wind, and sea level rise. The Climate Smart Healthcare report includes detailed considerations for climate resilient design of healthcare facilities. Existing healthcare buildings and infrastructure (e.g. water and energy supplies) need to be assessed for their vulnerability to extreme weather and sea level rise, with responses ranging from alterations, adaptive usage plans, to planning for retreat and replacement (Wardekker et al. 2012). For example, as part of the PAHO/WHO Smart Hospitals initiative, Georgetown Hospital in St Vincent and the Grenadines has had roof repairs, solar panels installed, upgraded plumbing, water storage, and energy systems to improve its resilience to hurricanes in the Caribbean that are becoming increasingly severe, while at the same time, reducing energy consumption. In 2013, the newly refurbished hospital (Fig. 2.9.4) remained open when a severe storm closed most other health services. Georgetown Hospital continued to function, while also supplying clean rainwater to local community members (Pan American Health Organization & Regional Office for the Americas of the World Health Organization, n.d.).

Fig. 2.9.4 Georgetown Hospital, St Vincent, and the Grenadines (PAHO/WHO).

The need for increased service investment in public health early warning systems for heatwaves and other climate-related hazards has already been highlighted. Context-specific responses specifically related to infectious disease have also been developed (Confalonieri et al. 2015). These include enhanced disease surveillance, epidemic early warning systems, and new wider control efforts such as mosquito surveillance and standing water management which perhaps have not previously been needed. Changing patterns of disease may also require re-balancing of the healthcare workforce, as well as workforce re-training about new diseases.

Greater attention has been paid to reducing the health sector's own substantial greenhouse gas emissions. Although much of the focus has been in high-income countries, the Climate Smart Healthcare report points out the contribution that low-carbon changes can make to improving access to healthcare in low-income, energy-insecure settings. England, the United States, and Australia have all estimated the total emissions footprint of their healthcare sectors, with findings ranging from 3% to 10% of total national emissions (Malik et al. 2018). While the scope of these assessments varies, emissions come mainly from hospital energy use, the procurement of

material resources (particularly pharmaceuticals), and healthcare-related transport. Hospitals and health boards are often the largest employers and procurers in a region, and can therefore influence local government policy, large numbers of employees, and wider supply chains, putting them in positions of significant regional leadership.

In England, the National Health Service has a dedicated Sustainable Development Unit, whose task it is to reduce the overall environmental pollution from healthcare, with a focus on climate pollution. By taking a systematic approach to measuring emissions, setting long-term and intermediate targets, and taking action on energy, travel, reducing waste in procurement and influencing supply chains, emissions reductions have been achieved, coupled with financial savings of about GBP30 million per year (NHS Sustainable Development Unit 2016). Despite an 18% increase in inpatient admissions between 2007 and 2015, NHS England reduced its greenhouse gas emissions by 11%. Their ‘wedges’ approach demonstrates how within-health sector measures will need to be coupled with partnerships beyond the health sector to achieve required reductions (Fig. 2.9.5). The NHS England example also demonstrates the importance of the national regulatory context—in this case the UK Climate Change Act 2008 has set a consistent regulatory framework requiring all sectors to reduce their emissions by 80% by 2050 (Climate Change Act 2008 (c.27) 2008).

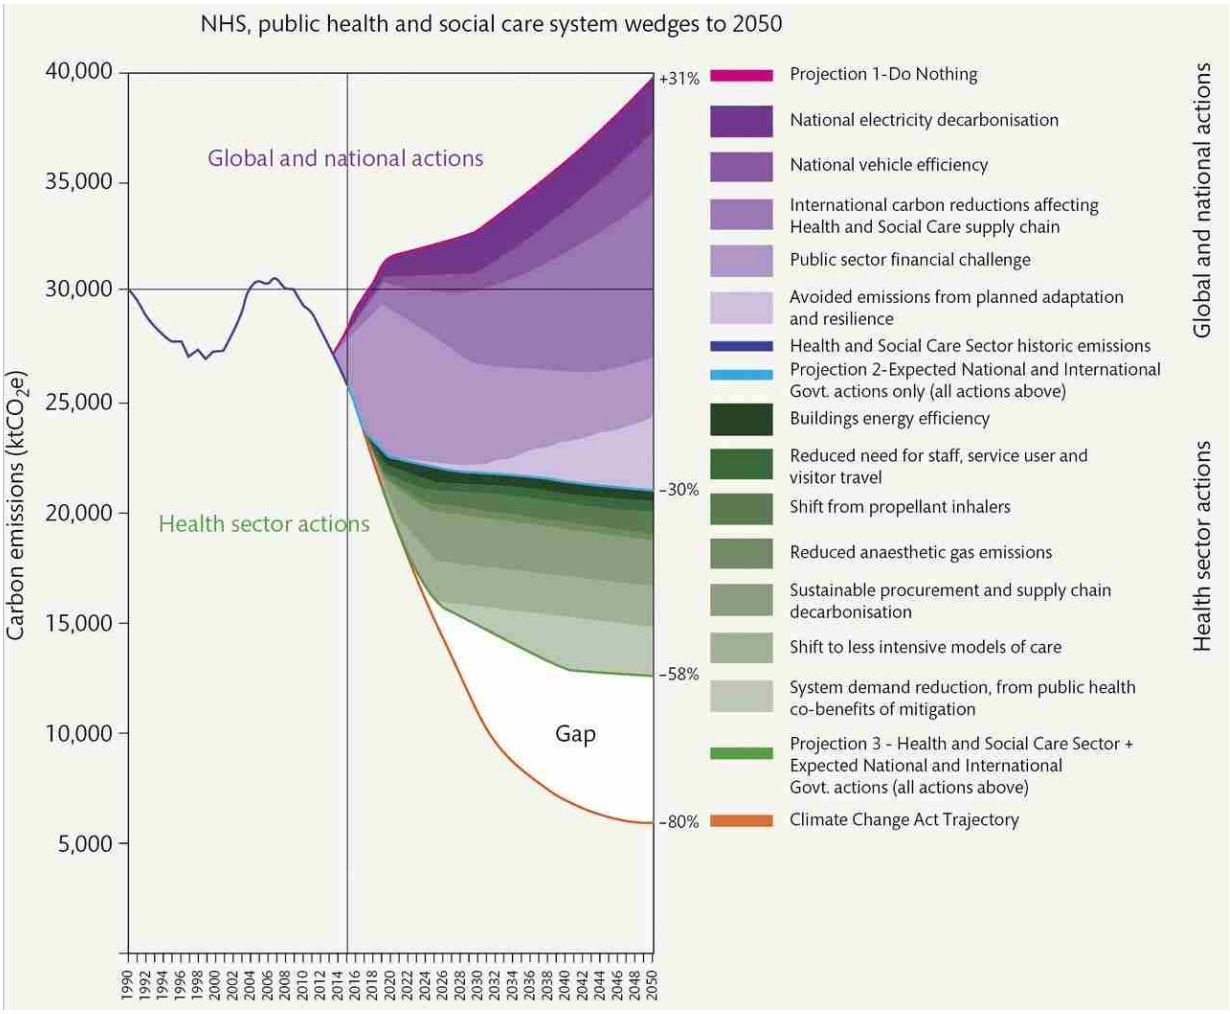

Fig. 2.9.5 NHS England, public health and social care system ‘wedges’ to 2050.

Mitigation: scale, possible co-benefits, and unintended harms

To avoid dangerous climate change, greenhouse gas emissions must fall to net zero in the coming decades, requiring an industrial and energy revolution. In the past, energy revolutions have been disruptive. They have caused serious environmental damage, increased social inequalities, and shortened life expectancy. Are there paths to a low-carbon future that can achieve the opposite result—simultaneous improvements in the quality of the environment, public health, and health equity? We will review the

evidence for common solutions and discuss ways in which ‘co-benefits’ might influence policy settings for climate change.

If warming by the end of the century is to be contained to below 2°C, then CO_2 emissions must be reduced to around 14 Gt per year in 2050, less than a quarter of ‘business as usual’ projections. This is a tall order, and if reductions of such magnitude are going to be achieved, there will need to be radical changes in the way humans use energy across all sectors, including housing, transport, industry, and food and agriculture. It will require deeper social changes than merely identifying and bringing forward renewable technologies. Despite rapid growth in alternative energy sources, over the last 50 years each added unit of energy from wind, hydro, and other renewables has displaced only a quarter of a unit of energy obtained from fossil fuels and has had an even smaller impact on electricity generation (York 2012). In order to meet greenhouse targets, there must be serious deterrents to fossil fuel use, including prices that reflect the full environmental and social cost.

The 2010 World Development Report talked about changes that are so large they constitute ‘an energy revolution’. Revolutions may re-orient society in a way that is beneficial, in the long run, but they tend to be disruptive and harmful in the short term. The last energy revolution began in England in the nineteenth century and ushered in what has been in many respects a golden age of industrialization and improvements in life expectancy. But England, and every other country that went through the process, also experienced the ‘four Ds’—disruption, deprivation, disease, and death (Szreter 2004). In the large English cities in the 1840s, crowding, pollution, and social upheaval affected everyone, but particularly those at the bottom of the social hierarchy. Life expectancy at birth fell to medieval levels, less than 30 years among the working classes in many cities (Szreter and Mooney 1998).

The challenge with climate change mitigation will be to disrupt present patterns of energy use, while avoiding the very high and inequitable social and health costs that were carried by nineteenth-century cities. Early experience with alternative energy sources has not been altogether reassuring. One stark example is the encouragement of biofuels, which exemplifies the potential for health, equity, and environmental co-harms in a poorly designed low-carbon transition. There have been large-scale moves to use food and vegetable oil crops for bioethanol and biodiesel, often with

substantial government subsidies: in 2009 about a quarter of all US corn was diverted to biofuel production as a result of federal intervention. Their effectiveness for reducing greenhouse gas emissions is questionable, and their encouragement has increased competition for food staples such as soybeans, maize, and cereals—increasing biofuel demand accounted for between a quarter and a third of the rise in global grain prices in the early 2000s, and played a significant role in the 2006–2008 food price crisis (Malins 2017). It remains to be seen whether second-generation biofuels, extracted from non-edible plants such as jatropha that are grown on marginal lands and don't compete directly with food production, will bring the same energy benefits without the health risks.

It is possible to identify low-risk transitions to zero carbon that can enhance rather than worsen health and equity. One easy example is provided by the link between short-lived climate pollutants (SLCPs) and air quality. Black carbon (soot) particles, ozone, and methane have stronger heat-trapping properties than CO_2 on a weight-for-weight basis, but have much shorter atmospheric life spans (from days to decades) (Kerr 2013). SLCPs, especially black carbon and ozone, are also responsible for a large proportion of the 7 million deaths globally due to air pollution.

The United Nations Environment Programme estimated what could be achieved by widespread application of measures that are proven to reduce black carbon and methane (United Nations Environment Programme 2011). These measures include particle filters for disease engines, clean burning biomass cook stoves, and bans on the open field burning of agricultural waste. Assuming full implementation by 2030, the effects compared with 'business as usual' emissions amounted to saving 0.5°C of warming in 2050, while the reduction in local pollution would save about 50 million tonnes per year of lost crop yields, and avoid about 2.5 million premature deaths worldwide. The World Health Organization built on this work to identify priority policies with the best co-benefits for health and climate change mitigation through reductions in SLCPs. They identified four mitigation strategies with the greatest potential to effectively reduce SLCPs and achieve large health benefits: supporting active travel including through rapid mass public transport; promoting healthy plant-based diets; low-emission cook stoves and reducing household solid fuel use; and stricter vehicle emissions and efficiency standards, including for freight vehicles (World Health Organization 2015).

More broadly than just SLCPs and air pollution, there are potential health and equity co-benefits from well-designed climate action across all the major emissions sectors. Transport and housing are two sectors where health co-benefits have been well studied, but where there is also a risk of adverse consequences for health and/or health equity if interventions are not carefully designed. One example is the health and energy efficiency benefits of home insulation and efficient heating. In New Zealand, although the climate is moderate, many homes are relatively cold and damp owing to a lack of insulation, ineffective heating, and poor building design. A randomized community trial tested the effect of home insulation on indoor temperatures, energy consumption, and respiratory health (Howden-Chapman et al. 2007). Insulated homes were found to be warmer, drier, used 20% less electricity than the control homes, and children in them were sick less frequently (Table 2.9.1). The findings led subsequently to a national roll-out of insulation subsidies and installation.

However, alterations to improve the energy efficiency of housing may increase a range of other health risks. For example, there is a balance in houses between airtightness and ventilation that provides for efficient warming while allowing for adequate air flow to reduce indoor air pollution and prevent moisture from reaching levels conducive to mould growth (Shrubsole et al. 2014). The complex connections between housing, health, health equity, and energy efficiency require methods that allow for policies to be tested against their integrated impacts over time, as has been recently successfully tested for UK policies about housing (Macmillan et al. 2016) (Table 2.9.2).

Table 2.9.2 Outcomes of a randomized trial of insulation in 1350 New Zealand households. All households included one or more children with asthma

	Outcome
Average bedroom temperature in winter	Warmer by 0.5 degrees
Relative humidity in bedroom	Reduced by 2.3%
Energy consumption	81% of controls
Self-reported wheeze	OR 0.57 (0.47–0.70)
Days off school	OR 0.49 (0.31–0.80)
Visits to general practitioner	OR 0.73 (0.52–0.87)

OR, odds ratio.

Source: data from Howden-Chapman P et al., Effect of insulating existing houses on health inequality: cluster randomised study in the community, *British Medical Journal*, Volume 3, Issue 334, pp. 460, Copyright © 2007, DOI: 10.1136/bmj.39070.573032.80.

In many countries, emissions from the transport sector are growing more rapidly than those from any other sector. Yet there are many opportunities in transport policy to simultaneously cut carbon and improve health. This is particularly so in cities that are currently highly car-dependent. For example, in New Zealand about 80% of travel is by private car, and yet many vehicle trips, in the city, cover very short distances. In the New Zealand Household Travel Survey 2003–2006, it was reported that about three-quarters of car trips in urban areas were 7 km or less, and almost a third (31%) were 2 km or less. A system dynamics modelling study assessed the potential health and climate change co-benefits for investing in cycling infrastructure in New Zealand's largest city for a range of outcomes over a 40-year period (Macmillan et al. 2014). Even modest improvements in the provision for cycling in the city was estimated to have a cumulative net benefit of hundreds of millions of NZ dollars across air pollution, car crash injuries, physical inactivity, fuel costs to households, and greenhouse gas emissions, with the greatest savings through reductions in mortality due to physical inactivity. These were only marginally offset by an increase in cyclist injuries. With widespread best practice cycling infrastructure, much greater benefits were estimated, in the order of ten billion NZ dollars, through a

more substantial mode shift from car use to cycling, and greater improvements in the safety of cycling. Mortality benefits in this scenario outweighed injury deaths by more than 15 to 1.

A similar modelling exercise was undertaken in Delhi, India, comparing the health effects of different mitigation strategies (Woodcock et al. 2009). The city has set targets for greenhouse gas emission reduction, and this could be achieved by increasing the numbers of low-carbon vehicles, encouraging more active transport (walking and cycling), or a combination. The low-carbon vehicle option would avoid premature deaths and illness, mainly as a result of reduced air pollution in the city, but it was estimated these co-benefits were roughly ten times less than what could be achieved by the 'active transport' or 'combined' strategies.

In summary, global greenhouse gas emissions need to be reduced to about zero by 2050 to provide a reasonable chance of holding warming by the end of the century to 2°C or less. Radical mitigation of this kind might be seriously health damaging. But there are opportunities for co-benefits: well-chosen interventions could produce health gains (early), as well as long-term climate security. Although we have dealt with mitigation and adaptation separately in this chapter, it is clear that activities to adapt and reduce emissions need to be integrated, so that one does not undermine the other, and the potential for multisolving can be maximized. Despite our well-honed knowledge about climate science, substantial evidence for health impacts and potential for health and equity gains in action, there continues to be substantial inertia by governments, institutions, and organizations who are required to make urgent change. In the final section, we use a public health lens to reflect on obstacles to action on climate change, and why placing health at the centre of the discourse may hasten progress.

Answers to the carbon IQ quiz

Without greenhouse gases, the temperature at the Earth's surface would be below freezing (about 15°C). The global average is instead about +15°C. The answer is A.

Climate is long-range weather, over a timescale of decades. The British Meteorological Office, for example, uses 30 years as the averaging period, though in some recent assessments 20 years of weather has been considered long enough to define a climate. The answer is C.

C is closest to the mark: today's choices about the level of emissions will have long-term consequences (Stouffer 2012). AR4 says 'about 50% of a CO_2 increase will be removed from the atmosphere within 30 years, and a further 30% will be removed within a few centuries. The remaining 20% may stay in the atmosphere for many thousands of years' (IPCC 2007). There are many caveats, because the various processes that soak up carbon work at different speeds, and on a large scale, the lifetime of CO_2 depends on the amount emitted, and the rate of emission. But as a rough guide, about 40% is likely to be still in the atmosphere after 100 years, and just over 20% after 1,000 years.

Combustion of biomass releases a complex soup of pollutants, and reactions in the atmosphere generate 'secondary' agents such as ozone and other photochemical oxidants. The effects on climate are complex. Black carbon absorbs heat; sulphur aerosols have a reflective (cooling) effect. Because these agents are short-lived (remaining in the atmosphere for days or weeks), the impact is local/regional. Deposition of soot on ice causes increased absorption of solar energy, and accelerated melt. The answer is E.

The oceans absorb 80–90% of the solar energy that is trapped by greenhouse gases. Additional amounts of heat go towards melting glaciers and sea ice, as well as warming the land and parts of the atmosphere. Only a tiny fraction warms the air at the planet's surface.

As of early 2018, 2016 has the title of warmest year on record. Some have argued that the answer is 1260 (the period of the medieval warming) but this is not true.

Laos emits about 0.2 tonnes CO_2 per head per year. A 747 jet emits about 100 g of CO_2 per passenger kilometre (Carbon Independent 2015). Singapore to Rome return is roughly 10,000 km, which amounts to about 1 tonne CO_2 per passenger, based solely on the fuel consumed during the flight. Note that this does not allow for the greater warming effect of CO_2

released high in the atmosphere, nor the embedded fossil fuel costs of aviation, which include those incurred in building jets, running airports, and training staff. But on this basis the solution is 0.2 and the best answer is D.
A cyclist would travel 570 km on a litre of comparably energy dense food, which is 0.2 L/100 km (Wilson 2004). But this refers to a racing cyclist moving at 30 kph. Note that wind resistance falls away rapidly as speed drops—less than half the energy would be required for travel at an average of 20 kph (which means no more than 100 ml of oil-equivalent per 100 km).
George H.W. Bush made this commitment at the Rio Summit in 1992, after signing the UN Framework Convention on Climate Change. In the subsequent 20 years Republican leaders have shifted their ground, and increasingly they have denied that climate change is a serious threat (Oreskes and Conway 2010).
The Arctic is not cooling—temperatures are rising in this part of the world more rapidly than anywhere. The effects of climate change on rainfall are mixed—in some places conditions will be wetter than before, elsewhere precipitation will reduce. But overall the world will be a wetter place, with more intense rainfall than before, as a consequence of a warmer atmosphere carrying more moisture. The ocean will not become less acidic—increased uptake of CO_2 is expected to double the concentration of H+ ions by early in the twenty-first century. And the stratosphere is cooling, not warming, as a result of the thickening greenhouse blanket. The answer is D.

Impediments to action

More than 30 years have passed since scientists first pointed out the heating effects of rising greenhouse gas concentrations in the lower atmosphere. The United Nations Framework Convention on Climate Change was signed in 1992. Since then evidence of disruption and risk has accumulated, and the IPCC has reported, in detail, every 6 years or so on the impacts of climate change and the most effective means of adaptation and mitigation. Yet some governments appear to be more firmly opposed to taking action than their predecessors 25 years ago, and emissions continue to rise, worldwide. Why?

We suggest it is important to bear in mind the nature of the problem. Climate change results from two things, the success of a culture that equates progress with consumption and an economic model that ignores

environmental costs. The implications of climate science therefore are deeply threatening to political and commercial interests that are invested in the status quo. It is scarcely surprising that resistance has hardened over 30 years, as our knowledge about causes and consequences has increased. It is possible to tweak the present machinery to limit environmental damage without too much political disturbance (replacing petrol cars with electric cars or installing efficient lighting, for instance). But deep changes, of the kind needed to restrict warming to what has been agreed internationally, must be transformational. This is a much bigger challenge, technically, socially, and politically. There are of course other factors that make it difficult to progress more quickly in sustainable, low-carbon directions. These include development 'overhang' with a large fraction of the world's population requiring rapid access to energy and services; psychological responses to distant risks; doubt inflamed by powerful vested interests via media and politics; governance structures not well suited to long-term challenge; and modes of scientific research that privilege reductionist thinking.

But there are some grounds for optimism. The Paris Agreement was a milestone, internationally. Although it includes no legal sanctions to enforce emission reduction, and the independent nationally determined contributions (INDCs) that were promised by signatories are not enough on their own to hold warming to 2 degrees, the 2015 agreement is a necessary step in the right direction. There was for the first time international consensus on actions that need to be taken, and agreement to a process of regular review and reporting. And there are signs of effective action at local level also. For instance, cities, leaders in the public health response to the last energy revolution—the arrival of steam power and the Industrial Revolution, are once more taking a major role in innovation, collaboration, and the implantation of climate policy.

There is evidence that re-framing climate change as a health issue, as opposed to an 'environmental' issue, may increase societal willingness to act (Myers et al. 2012). Health professionals hold positions of privilege and influence, and in the past, when faced with big, difficult, threatening issues, have been thought-leaders and advocates. Consider tobacco, nuclear weapons, and the social determinants of health. It is time, we conclude, to add climate change to this list.

Conclusion

Climate change is a new kind of environmental problem—the scale of the phenomenon dwarfs the issues that public health workers have encountered previously. Its effects on health will result, mainly, from exacerbating disease and injury from familiar causes. Understanding how multiple variables will interact in the future to diminish or magnify the effects of climate change on health requires methods not currently familiar in public health. Complex models are needed that can incorporate non-linear interactions, feedbacks, and tipping points dynamically over time.

Climate change is undoubtedly an issue of health and social equity—those at greatest risk already carry a heavy load of disadvantage, and have contributed little to the CO_2 that now sits in the atmosphere. This means that many of the impacts can be avoided, or reduced in magnitude, by providing basic health improvements to the world's poor populations.

Targeted adaptation efforts, such as early warning systems and good disaster management, are necessary also: there is plenty of evidence that high-income countries are not immune from the effects on health of climate variability. But the world is not making rapid progress on either poverty reduction or targeted adaptation, so we expect the public health dimensions of climate change to become more prominent in the next few decades. In the medium to longer term (2050 and beyond), unless there are radical reductions in emissions beforehand, it is possible the average temperature of the globe will rise by more than 4°C over the pre-industrial baseline. If this happens, impacts of climate change may overwhelm all efforts at adaptation. For this reason, the response to climate change must be two-pronged—coping with adverse effects of rising temperatures and changing patterns of rainfall, and at the same time, finding ways of slashing emissions and reducing levels of climate active pollutants in the atmosphere. On the positive side, well-chosen adaptation and mitigation measures may achieve substantial health gains. Strengthening the place of public health in multidisciplinary decision-making about climate change can assist with identifying low-risk climate paths that enhance rather than worsen health and equity.

Behavioural determinants of health and disease

Lawrence W. Green, Kristin S. Hoeft, and Robert A. Hiatt

Scope of behavioural determinants of health and disease

Behaviour, and its more robust expressions, ‘lifestyle’, cultural and social ‘norms’ are widely implicated in disease incidence and prevalence. That behaviour is associated with health and disease has never been in doubt. Indeed, the tendency to blame sinful, negligent, indulgent, ignorant, reckless, slothful, or selfish behaviour for health problems has too often placed undue emphasis on individual responsibility and culpability when the solution to health problems of populations demanded attention to the social and physical environment. But no matter how behaviour is framed or moralized in relation to its causes, it remains an inescapable variable in the pathway between ultimate upstream determinants and the incidence or prevalence of most diseases and health conditions downstream. Approaches to public health have sought throughout the history of civilization to: (1) control or cajole the health-related behaviour of individuals; (2) protect individuals from the behaviour of others; and (3) mobilize the behaviour of groups to influence a population’s health-related understanding, beliefs, attitudes, values, policies, organizations, and social or physical environments.

This chapter reviews ways in which behaviour relates to the spectrum of health and disease determinants, from environmental to genetic, in shaping health outcomes. It builds on the previous chapters in recognizing the powerful influence of socioeconomic and cultural factors, especially poverty and discrimination, in influencing both behaviour and health. Many commentaries in the past four decades have attempted to correct the overemphasis on individual behavioural determinants of health by discounting and sometimes disparaging any focus on individual behaviour or personal responsibility in disease prevention and health promotion, often

referring to it as ‘victim blaming’ (e.g. Steele et al. 2014), and on another side, ‘scapegoating’ people with health problems as the cause of rising costs of healthcare (e.g. Minkler 1983). This chapter seeks a middle ground, building on the growing understanding of the ecological and cultural context of the behaviour–health relationship. It seeks to integrate that knowledge in an approach to public health that acknowledges the reciprocal determinism of behavioural, environmental, and biological determinants rather than minimizing the importance of behaviour in these complex interactions. This is consistent with a concept of ‘behavioural justice’ that Adler and Stewart (2009, p. 49) refer to as a ‘principle that individuals are responsible for engaging in health-promoting behaviours but should be held accountable only when they have adequate resources to do so. This perspective maintains both individuals’ control and accountability for behaviours and society’s responsibility to provide health-promoting environments’.

The role of behaviour as a determinant of health and disease: from discrete to complex, from individual to society

Behaviour is defined as actions by individuals or groups, and occur everywhere throughout human society—from an individual action that affects only oneself, to behaviours carried out by healthcare providers, to behaviours and decisions that are enacted at social, environment and policy levels that have widespread impact on health directly and indirectly through shaping individual behaviour and policies. While recognizing that socioeconomic status is a very strong influence on health behaviour, we first we discuss health behaviour more broadly, and then discuss socioeconomic status in relation to health behaviour in detail in the later sections of the chapter.

Some health behaviours are single, discrete actions that can have lasting effects for health (e.g. getting a vaccine, or a mosquito net to reduce malaria exposure) or injury (e.g. texting while driving). However much of today’s growing chronic disease burden relates more to complex repeated behaviours, sometimes referred to as ‘habit’ or ‘lifestyle’. We use the term ‘complex behaviour’ to refer to combinations of interrelated practices and their environmental contexts, reflecting patterns of living influenced by the family and social history of individuals and communities, their

environmental and socioeconomic circumstances, and their exposure to cultures and communications.

Public health practitioners have to think about behavioural determinants of health and disease while also considering how to encourage behaviours that improve health and discourage those that threaten it, through public health programmes, policies, or interventions. We know that discrete behaviours can be more easily influenced directly by health education targeted at individuals and groups. Complex behaviour, however, changes more slowly and usually requires some combination of educational, organizational, economic, and environmental interventions in support of changes in both behaviour and conditions of living. This combination of strategies has defined health promotion and public health programmes addressing complex behaviour change through combined efforts to predispose, enable, and reinforce the behaviours (Swan et al. 2012; Green et al. 2019). The predisposing interventions are directed particularly at the individual, but the enabling and reinforcing interventions are directed at policies in support of, and environments in which, predisposed individuals would seek to enact and maintain the behaviour.

HIV/AIDS is a disease that relies for prevention on complex behaviours, while awaiting discrete solutions (e.g. vaccine). Virtually every public health breakthrough has had a behavioural change process that served the public until the technology was at hand. Then, behavioural change processes were needed to diffuse, adapt, and apply the new technology to varying cultural and social circumstances. Until an HIV vaccine is developed, society must depend on behavioural preventive measures to curb its spread. These include, of course, policies, environmental changes, and health educational programmes that support behavioural changes (Krishnaratne et al. 2016).

Much of the early success in controlling HIV infections through change in sexual practices (especially use of condoms) among men in urban gay communities appears to have been in response to health education programmes (Petrow 1990). Reviews also show increases in the use of clean needles for at least 15 years among intravenous drug users (e.g. Wodak 2006), which has required a combination of policy and educational interventions to make clean needles accessible and more acceptable than the culture of needle sharing. An HIV outbreak in rural Indiana attributed to needle sharing among injecting drug users underscored the importance of continued reinforcement of known best practices (Conrad et al. 2015).

Medical advances such as antiretroviral therapy (ART) and pre-exposure prophylaxis (PrEP) for HIV prevention still involve complex behaviours that require daily regimens for optimum efficacy (Wilton et al. 2015; Krishnaratne et al. 2016). Attempts to minimize or circumvent the need for behaviour change, as with adult male circumcision in Africa, present additional challenges of bush surgery complications, and false assumptions that one may now ignore the admonitions about safe sex (Green et al. 2010).

Specific behaviours and health—the causal links

When identifying behavioural risk and protective factors for a given health condition, one must evaluate the scientific evidence supporting causal links between behaviours and health outcomes. The shorter and more direct (proximal) the link is, the easier it is to identify. Some behaviour clearly increases the risk of developing disease and can be considered a proximal cause of disease, such as unhygienic practices that expose one to infections. Examining the correlations between specific behavioural and social patterns and indicators of health and disease status provides the foundation for assessing behavioural factors as population health determinants (Evans et al. 1994). Examining the covariation of these relationships with other characteristics of the populations and their environmental circumstances helps put behaviour into its ecological, social, and cultural context (Institute of Medicine 2012).

The causal link is relatively easy to establish for single-agent communicable or infectious diseases. Evidence from observational epidemiological studies, human experimental trials, and animal models, together with clear mechanisms of biological action, lead one to conclude that many behaviours are, in fact, contributing causes (causal risk factors) of specific diseases. Again, the easiest examples of clear causal linkages are those established for single-action, discrete behaviours such as ingesting a contaminated food, getting an immunization that confers lifetime immunity, or taking a one-dose medication that leads to rapidly improved symptoms. As the number of booster shots required for immunization or doses required for cure increases, for example, the behaviour becomes more complex, requiring repetition or timing, and the causal linkage more difficult to unravel among the biomedical agent, the behaviour, and all the other events

and circumstances that might have intervened and influenced the person's exposure, susceptibility, and outcome along the way.

Complex behaviours and health—the synergistic causal pathways

Other, less discrete, behaviours correlate with and precede better health, increased longevity, and decreased disease risk, but their causal link is more tenuous, variable, delayed, cumulative, or indirect, warranting their inclusion with more distal determinants. Examples include the development of dietary and physical activity patterns. More difficult still are causal pathways that are long and indirect, such as long-term behavioural patterns that are not under medical supervision and relate to multiple-cause chronic diseases and conditions (Krieger 1984; Glass and McAtee 2006). We present two examples of evidence supporting causal links between complex behaviours and coronary heart disease: smoking and physical inactivity. These examples illustrate that even in the absence of direct experimental evidence in human beings, strong evidence of other types can be combined for the steps in a causal chain from behaviour through physiological effects to disease or health. In addition, the synergistic effects of two or more behaviours on health outcomes have been established.

A plausible biological model of the relationship between smoking behaviour and coronary heart disease has been available for decades (Dawber 1960). Observational epidemiological studies—including within- and between-population designs, case–control, and prospective designs—produced strong and consistent measures of association, the hypothesized temporal sequence, and dose–response relationships in subsequent decades (Stamler 2005). Additional randomized trials have included smoking cessation programmes that provide experimental evidence for smoking as a cause of coronary heart disease. Although the overall results of the Multiple Risk Factor Intervention Trial (MRFIT) in the United States were disappointing, in both MRFIT (Ockene et al. 1990) and the British trial on the effect of smoking reduction (Rose and Colwell 1992), cessation interventions showed decreases in coronary heart disease mortality respectively of 13% after 20 years and 12% after 10.5 years. In addition, when smokers at baseline from the experimental and control groups were pooled, quitters had a significant decrease in their risk of mortality from

coronary heart disease compared with non-quitters (Ockene et al. 1990). As the smoking landscape shifts with development of electronic cigarettes and heat-not-burn tobacco products, researchers and regulators are striving to determine the individual and public health risks associated with the new products (Levy et al. 2017).

Physical inactivity as a risk factor for coronary heart disease is the second example. Evidence that physical inactivity contributes to coronary heart disease came from studies of the biological effects of exercise on cardiovascular physiology, observational epidemiological studies, and randomized controlled trials of physical activity and physiological coronary heart disease risk factors, such as high blood pressure, obesity, and diabetes. The biological effects of exercise training to enhance cardiovascular health were well-established by the 1980s (McArdle et al. 1986). Epidemiological evidence continues to show consistent and relatively strong associations, the hypothesized temporal sequence, and a dose–response relationship between physical activity and coronary heart disease (Ahmed et al. 2012). Observational epidemiological studies and randomized controlled trials demonstrated the beneficial effects of physical activity on blood pressure (Arroll and Beaglehole 1992) and on blood lipids and lipoproteins (Lokey and Tran 1989), which have, in turn, been causally linked with subsequent coronary heart disease. The combination of these sources of evidence for each of the steps in a causal chain provides a plausible model for the sequence.

Some of the immediate causal risk factors are not themselves behaviours, but have determinants that are behaviours. In these cases, the behavioural determinants can be regarded as indirect risk factors that act earlier in the causal pathway. For example, a combination of overeating and sedentary behaviour produces high caloric intake and low energy output, which together mediate the behavioural determinants of obesity. Obesity, in turn, is a physiological risk factor for cardiovascular diseases (CVD) and type 2 diabetes (Institute of Medicine 2012).

Behaviour also contributes to the prognosis of diseases at each stage where the screening, diagnosis, or the compliance with prescribed regimens of treatment or self-care affects outcomes. For example, the prognosis of breast cancer depends on the stage of disease at which the person obtains screening, diagnosis, and medical care. The prognosis for type 1 (insulin-dependent) diabetes depends on the patient’s compliance with his or her

insulin prescriptions. Because behaviour is so central to disease outcomes, a large literature on patient education and patient compliance with medical regimens has been catalogued and subjected to meta-analyses with regularity (e.g. US Preventive Services Task Force 1989 and continuously updated on https://www.uspreventiveservicestaskforce.org/BrowseRec/Index/browse-recommendations).

Behavioural risk factors in population health

The causal pathways by which behaviour can influence health (or its negative manifestations) can be broadly classified as direct (as shown by arrow 1 in Fig. 2.10.1) and indirect, where the indirect pathways (arrows 2 and 3 in Fig. 2.10.1) are largely mediated through the environment or through healthcare organization and personnel. These three determinants of health—behaviour, environment, and healthcare organization—in addition to human biology, were cast as the 'Health Field Concept' as part of the Lalonde Report on the Health of Canadians (Canada 1974), which many credit with having launched or at least facilitated the health promotion, health determinants and population health movements in public health (cf. Green and Allegrante 2011). The third indirect pathway could be drawn through genetics, the main pathway by which individuals can make some reproductive decisions partially independent of the medical care system, but such non-medically mediated decisions are largely mediated by the social environment, and increasingly involve the medical care system through genetic counselling. Figure 2.10.1 is useful guide, however it is hardly a full representation of the three determinants much less the genetic interactions, insofar as there is much reciprocal determinism between and among them. These environmental influences on behaviour will be examined in the next section, and behaviour's influence on the environment in a later section. Genetics are addressed in Chapter 8.19.

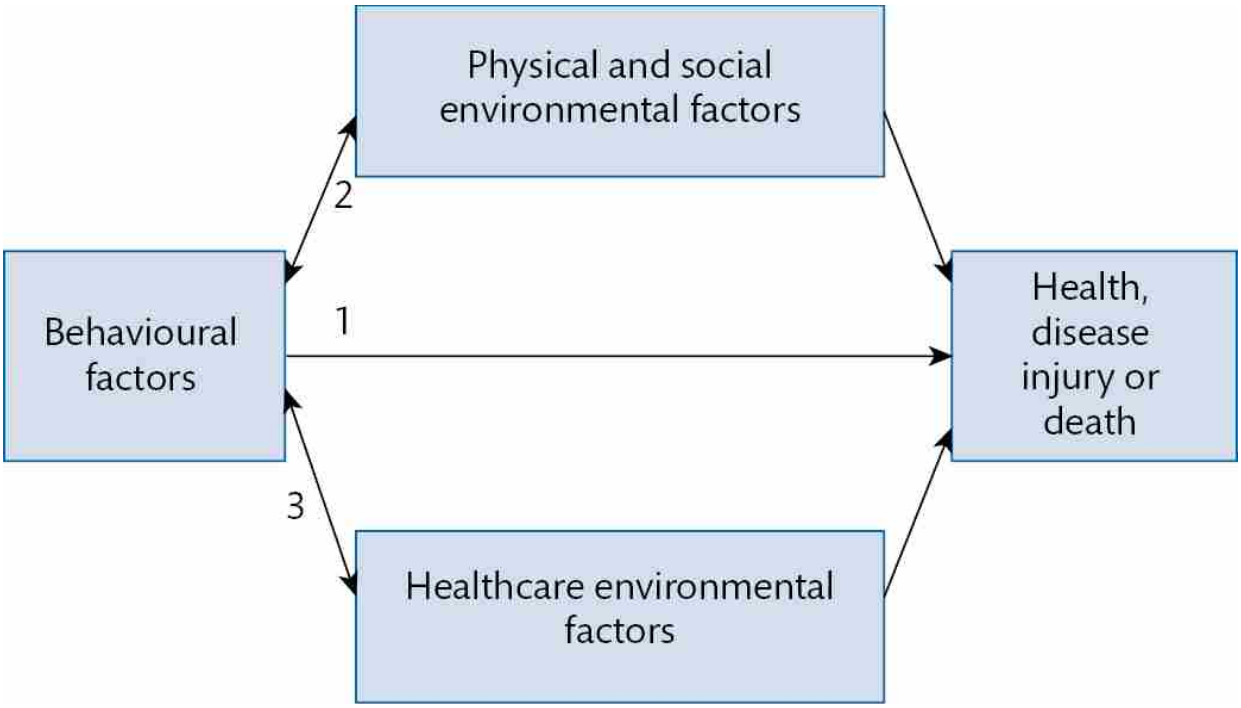

Fig. 2.10.1 Three pathways for behavioural influence on health, disease, injury, or death.

Behaviour itself as a risk factor for disease

The direct pathway suggested by arrow 1 in Fig. 2.10.1 includes the broad array of actions people take, consciously or unconsciously, that can have an immediate or cumulative effect on their health status. The effect on health may be intended (health-directed) or unintended (health-related), but the behaviour is nevertheless direct in its effect. The most dramatic of these are the violent injury-causing actions people may take behind the wheel of an automobile, with weapons, or unintentionally with the careless use of tools or toxic substances or merely walking absent-mindedly on a slippery or cluttered surface or while reading their cell phone screen. Less dramatic, but no less lethal, are the cumulative little actions people take each time they light a cigarette, imbibe or inject an addictive or mind-altering substance, or neglect physical activity or healthful foods.

Table 2.10.1 lists the five leading causes of death in most of the more developed countries, as reflected here by the United States, and relates those to the risk factors for each in column 2, which McGinnis and Foege (1993, 2004) and Mokdad et al. (2004) refer to as the ‘actual causes of death’. Colditz (2014) has noted that more than half of all cancer is a consequence

of behaviour, much of which is embedded in culture. Most of the risk factors in Table 2.10.1 are themselves behaviours. Those that are not behaviours themselves—such as high serum cholesterol, obesity, hypertension, and diabetes mellitus—are the physiological consequence, in large part, of behaviours. The behavioural determinants of risk factors in column 3 present some of the most challenging targets for public health intervention, because they require decreasing behaviours that are perceived as pleasurable (e.g. types of food, sedentary entertainment, casual or spontaneous sexual encounters) and increasing behaviours perceived as boring, painful, or inconvenient (e.g. less sugary or salty foods, more strenuous or frequent physical activity, use of condoms). Their challenges are compounded by the fact that most of the instances of these behavioural determinants of risk can be carried out very privately with limited opportunity for monitoring, enforcement, or social influence.

Tobacco consumption alone accounts for a large proportion of deaths, implicated as a direct risk factor in four of the five of the leading causes of death shown in Table 2.10.1. At least one of the three main behavioural risk factors—smoking, dietary practices, and alcohol use—is causally related to each of the leading causes of death shown in Table 2.10.1. Active smoking has been established as a risk factor for lung and many other types of cancer, coronary heart disease, diabetes, stroke, and adverse pregnancy outcomes, such as low birth weight, premature rupture of membranes, and abruption placentae (US Department of Health and Human Services 2004). As examples of how the behaviour of some individuals can influence the health of others, passive smoking (i.e. exposure to environmental tobacco smoke) has been related to lung and breast cancer and other respiratory diseases, as an independent risk factor for coronary heart disease, and exposure to environmental tobacco smoke in the home has been associated with asthma, other respiratory conditions, and with ear infections in infants and children (US Department of Health and Human Services 2006; Johnson et al. 2014).

Table 2.10.1 Five leading causes of death (United States 2015), their generally accepted risk factors, and their behavioural determinants

Causes of death (age-adjusted death rates in the United States per 100,000 population)	Selected risk factors	Behavioural determinants of risk factors
Diseases of the heart (168.5)	Tobacco smoke	Smoking
	Sedentary living	Physical inactivity
	High serum cholesterol	High-fat diet, medication
	Obesity, diabetes mellitus	Diet, physical inactivity
	Hypertension	High-salt diet, medication
Cancer (158.5)	Smoking	Smoking
	Low-fibre diet	Low-fibre diet
	Physical inactivity	Physical inactivity
	Sexually transmitted infections	Sexual behaviours, HPV vaccination compliance
	Obesity	Diet, physical activity
	Hepatitis B	Vaccination compliance
	Hepatitis C	Safe sexual practices, avoid needle sharing
Chronic lower respiratory diseases (41.6)	Hypertension	High-salt diet, medication
	Atherosclerosis	Diet
	Smoking	Smoking
Unintentional injuries (e.g. motor-vehicle related deaths, falls and drug poisonings) (43.2)	Alcohol abuse	Alcohol use before or while driving
	No seat belt engaged	Seat belt non-use

Causes of death (age-adjusted death rates in the United States per 100,000 population)	Selected risk factors	Behavioural determinants of risk factors
	Unsafe driving	Behavioural distractions (e.g. smoking, texting) while driving; speeding
	Drug abuse	Drug use before or while driving
	Falls	
	Drug poisoning	
Stroke (37.6)	Atherosclerosis	Diet, aspirin
	Cholesterol management	Diet, medication

Source: data from National Center for Health Statistics, *Health, United States, 2016 with Chartbook on Long-term Trends in Health*, p. 2 and p. 18, 2016, available from https://www.cdc.gov/nchs/data/hus/hus16.pdf Risk factor data from Johnson et al. 2014.

As noted in previous chapters, the causes of death in developing countries differ from the patterns reflected in Table 2.10.1, although the demographic profiles are converging. World Health Organization (WHO 2017) estimates of the five leading causes of death for low-income countries have been respiratory diseases, diarrhoeal diseases, stroke, CVD, and HIV/AIDS. As tobacco use has increased and problems of overconsumption of sugars, starch, and fat have replaced some of the malnutrition problems in those countries, other chronic diseases, in addition to CVD, have increased. According to WHO (2005) projections, over 8 billion deaths will be due to tobacco in 2030 (Mathers and Loncar 2006). Because it is a known probable determinant of at least 25 diseases, and the most important determinant of some of the leading causes of death, tobacco use will cause 10% of all deaths globally. This alone warrants the concerted global attention to this behaviour that has been proposed by the Framework Convention on Tobacco Control (2003).

Behaviour as a determinant of other risk factors

Besides the cumulative effect of behaviours on physiological risk factors, such as the energy balance between calorie intake and physical activity producing weight gain, obesity, and hypertension, many of the health

consequences of behaviour are secondary to their impact on the immediate environment. Individuals are not merely the passive victims of the environments they inhabit or traverse. They are agents of change in those environments, and their ability to alter or control environmental threats to their own health and that of others increases with technological innovations, such as machinery, sanitation, and food chains. The growing capacity of individuals and groups to alter their environments through technological means, such as transport and roads that decrease risk of injury, while transport also produces negative consequences for their health when combined with alcohol or texting while driving, or reducing walking as a physical activity. Hence, health promotion and health protection have emphasized mobilizing individuals and groups to undertake personal conservation behaviours and collective actions to support policy changes and regulatory initiatives in support of more healthful environments and health behaviour in response to environmental circumstances.

Among the most striking differences in health between the high- and low-income countries are the perinatal–juvenile mortality rates which have decreased dramatically in high income countries, but are decreasing slower in low-income countries. Childhood mortality has long been associated with maternal education, poverty, technology change, and sanitation, thus the major public health goals in low-income nations have related to the provision of immunizations, access to a sufficient supply of clean water, the installation of proper sanitation facilities, increasing access to HIV treatment, and improving childhood and maternal mortality (WHO 2015). The United Nations has undertaken a resolution to think more broadly and holistically to improve child health first with its Millennium Development Goals (MDG), and now, ‘Transforming our world: the 2030 Agenda for Sustainable Development’ which aims to eliminate hunger and poverty by the year 2030. These environmental and age-specific or disease-specific health measures, however, achieve their intended health goals only to the extent that an informed population accepts and uses them properly. A report by the World Bank (1993) suggested that the single most important public health policy for developing countries lies in the improvement of the education of young girls. Better educated women have fewer children, who tend to be healthier and, in turn, better educated and able to respond to the technological advances offered by such environmental measures. They also become a better informed electorate to demand and support healthful

policies. However, globally, education of girls still falls short of their male counterparts, and advocacy around this issue continues, earning Malala Yousafzai a Nobel Peace Prize in 2014. In short, behaviour remains a critical mediator of the relationships between environmental measures and health outcomes, as well as the relationship between the health needs and the political actions to create the environmental changes.

The behaviour–policy link in the causal chains becomes more important as the chronic diseases become more prevalent in middle- and low-income countries. Inspection of the recent trends in the richest of the developing countries provides evidence that improvement of the socioeconomic condition is accompanied by a shift in mortality towards the chronic diseases and their behavioural risk factors reviewed earlier. In Mexico, for example, as early as 1991, infectious and parasitic diseases were only the fourth leading cause of death, following diseases of the heart, malignant neoplasms, and unintentional injuries. Low and middle income countries are now the primary target for market expansion for the multinational tobacco and convenience food companies (WHO 2008; Monteiro et al. 2013). Behaviour will be an issue both in personally resisting the temptations offered by these industries and in collective action to restrain their advertising, promotion, ingredients, and location.

Behaviour as a consequence of cognitions, environments, and genetics

Notwithstanding the implied simplicity of identifying a few behaviours that account for the majority of deaths in developed countries, those and other behaviours are highly complex, value-laden, and overdetermined. Most behavioural risk factors and healthcare behaviours as well, are the product of a variety of component behaviours, tasks, skills, or actions. For example, food consumption confronts most people with a chain of related behaviours: procuring and selecting food, planning menus or selecting from a menu, preparing or ordering foods, and eating with literally hundreds of food-related choices, including where to shop or eat, what to purchase or prepare, how to season food, and with whom to eat (Simons-Morton et al. 1986). One can identify similar chains of component behavioural choices for each of the other health behaviours identified in Table 2.10.1.

Not only are the behaviours complex, but each behaviour has numerous influences or determinants. Factors that influence behaviours can be grouped into three major categories (Green and Kreuter 2005; with adaptation from Andersen 1969): predisposing, enabling, and reinforcing, as shown in Fig. 2.10.2. Both positive and negative behaviours are predisposed, enabled, and reinforced by forces in the culture and the environment. This broad categorization has proved useful in public health programme planning (with more than 1,000 published applications, see http://lgreen.net/bibliog.htm for bibliography) because it groups the determinants of behaviour according to the major strategies used in public health to influence them. *Direct communications* through mass media, schools, worksites, other organizations, and through patient counselling in health clinics are used to influence the predisposing factors. *Indirect communications* through parents, teachers, clergy, community leaders, employers, peers, and others are used to strengthen the reinforcing factors with organizational rewards or social-normative influence. *Community organization*, *political activation*, and *training* strengthen the enabling factors by mobilizing and moving resources, policies, and building skills and capacities.

Predisposing factors

Predisposing factors reside in the individual and include attitudes, values, beliefs, and perceptions of need, but these are shaped over time by cultural and social exposures, which produce reinforcing factors (see later). Predisposing factors are those antecedents to behaviour that provide the rationale, motivation, or drive for an individual's or group's behaviour. They mostly fall in the psychological domain of determinants, though genetics and environment shape them across the lifespan. They include the cognitive and affective dimensions of knowing, feeling, believing, valuing, and having self-confidence or a sense of self-efficacy.

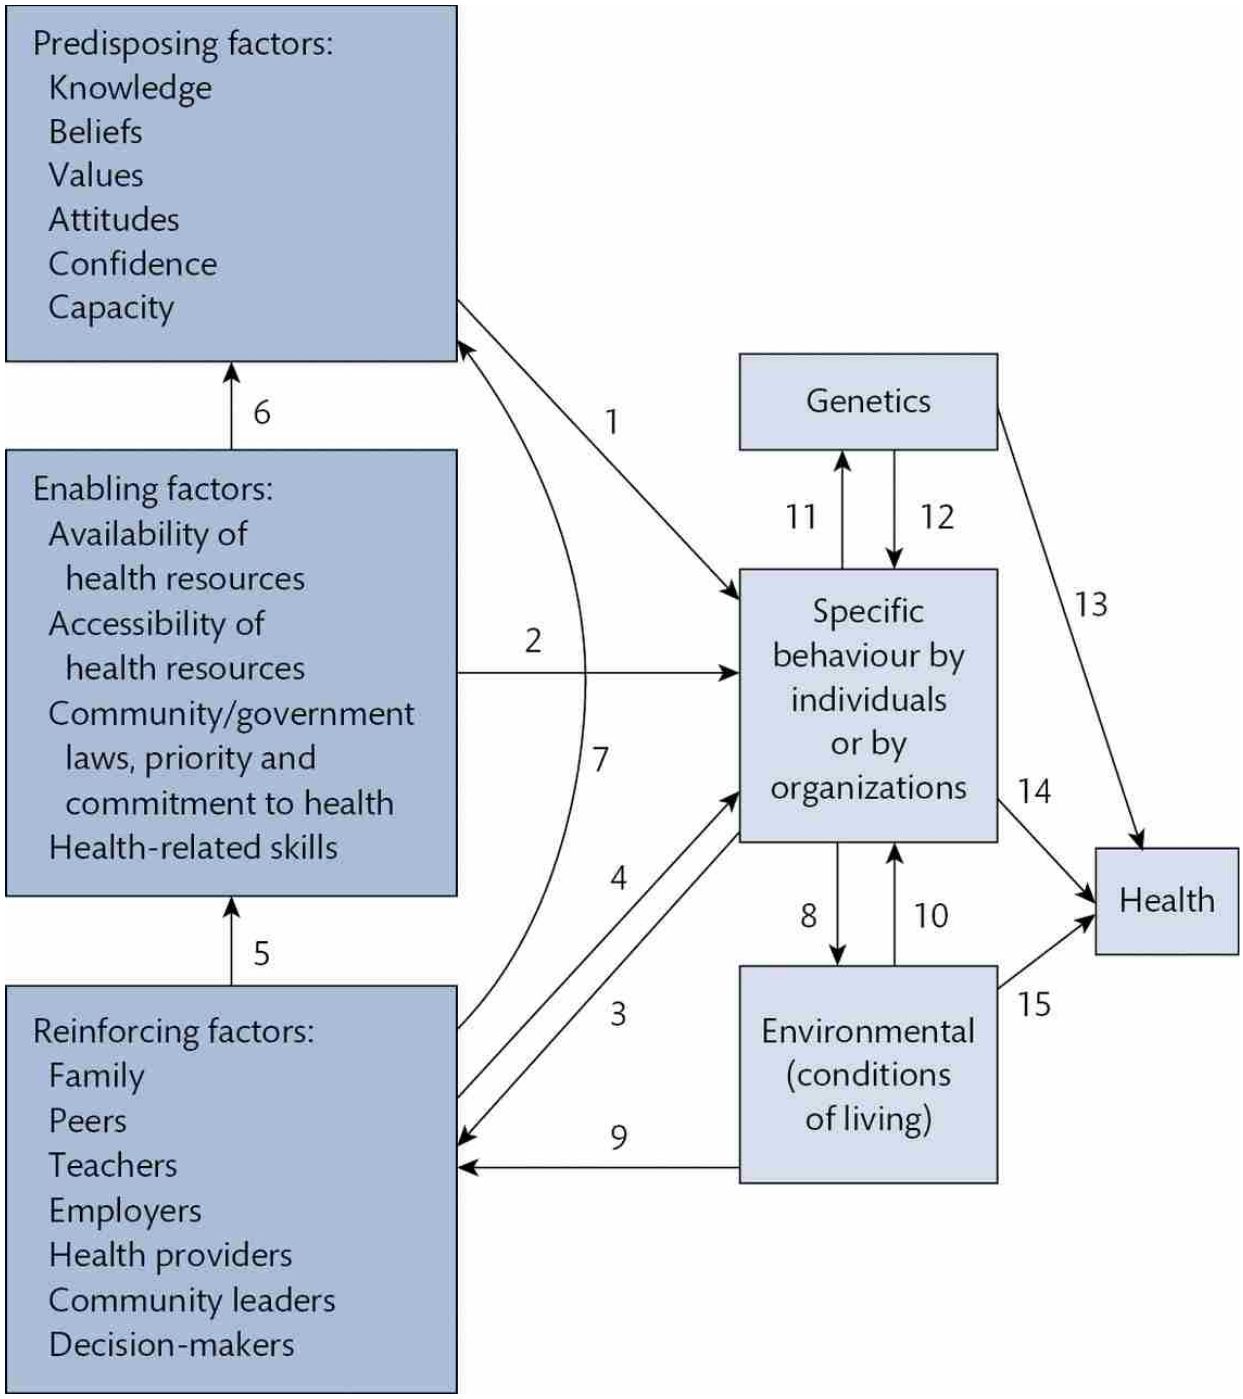

Fig. 2.10.2 This portion of the Precede–Proceed Model includes additional lines and arrows to outline a theory of causal relationships and order of causation and feedback loops for the three sets of factors influencing behaviour. In addition to the lines shown, an arrow from 'enabling factors' to 'environment' would elaborate the ecological aspect of factors that influence behaviour indirectly through changes in the environment.

From Green, L.W., Kreuter, M., Peterson, D., Geilen A., Eds. (2019). Health Program Planning: An Educational and Ecological Approach. Baltimore: Johns Hopkins University Press [in press, with permission of the author].

Because these determinants of behaviour reside in individuals, public health must seek to influence behaviour by assessing the prevalence and distribution of key predisposing factors and look for opportunities to communicate differentially with various segments of the populations, according to an educational diagnosis or 'social marketing' assessment of their knowledge, attitudes, values, beliefs, and perceptions. The behavioural science literature, especially in health psychology, is replete with competing theories of the relative importance of particular predisposing factors and how they interact with each other (e.g. Glanz et al. 2008). Some of these theories, such as the Health Belief Model (Becker 1974), Social Cognitive Theory (Bandura 2004), and the Transtheoretical Model of Stages of Change (Prochaska et al. 2002), have become mainstays of the intervention literature on health education and behaviour change. These frequent uses of selected models have produced sufficient numbers of comparable studies or programme evaluations to permit meta-analyses of their applications across different health behaviours (e.g. Spencer et al. 2005; Tuah et al. 2011). These applications of theory, in turn, have led to enough consistency in the construction of interventions and programmes that these have lent themselves to systematic reviews, notably by national panels such as the Task Force on Community Preventive Services (www.thecommunityguide.gov) and the UK's National Institute for Health and Care Excellence (http://www.nice.org.uk).

Enabling factors

Underplayed in most psychological studies of health behaviour, but critical to the role of public health as a complement to the roles of parents, schools, and mass media in the development of a healthy population, are the enabling factors influencing behaviour. These are often conditions of the environment that facilitate (or impede) the performance of a predisposition or motivated action by individuals or groups. Included are the availability, accessibility, and affordability of healthcare and community resources. Also included are conditions of living that act as facilitators or barriers to action, such as availability of transportation or childcare to release a parent from that responsibility long enough to participate in a health programme, clinic, or service. It also includes features of the built environment, such as bicycle lanes, sidewalks, proximity of housing to workplaces, and other physical

conditions of the environment that make physical activity more or less convenient and inviting (e.g. Taylor et al. 2007). Enabling factors also include new skills that a person needs—or new capacities that a group, organization, or community needs—to be able to accomplish health goals.

Public health addresses the enabling factors for behavioural change through policy changes and resource allocations at the national, regional, and local level, community organization for such policy and resource allocation at the local level when government programmes and services are insufficient or inappropriate to local perceptions of need. Training in the skills needed to take certain complicated actions is the other behavioural intervention used by public health to address the enabling factors.

In an era of constrained public health resources, many communities have resorted to more intensive community organization to build coalitions of multiple agencies including government and non-governmental organizations, and intersectoral collaboration between the health agencies and the community's schools, worksites, transportation, and other such sectors. Public–private collaboration on issues of enabling a more healthful food supply in school lunches, for example, or less accessibility of children to vending machines with cigarettes or 'junk food', have become increasingly common strategies for addressing the behaviour–environment interaction issues at the heart of most enabling factors (e.g. Institute of Medicine 2012).

Reinforcing factors

Before chronic diseases became the prevailing concern of public health in developed countries, behaviour was perceived as less important than today. The types of behaviour required to implement many of the most important public health interventions such as immunization and fluoridation of water supplies were less complex. Immunizations, for example, could confer long-term immunity for an individual with a single act. Fluoridation or chlorination of water supplies could be implemented in many communities with no engagement of the public, although when water fluoridation did become a local political issue requiring a local vote, the behaviour in question for most people was, again, a single action. As chronic diseases became more prevalent, the behaviours in question were largely ones that had to be repeated frequently, some for a lifetime, such as dietary practices,

hypertension medication regimens, smoking cessation, and physical activity. For these behaviours, the predisposing and enabling factors remain important, but reinforcing factors take on increased importance because maintaining a behaviour requires strong or repeated extrinsic reinforcement in the form of rewards or incentives, or highly internalized intrinsic reinforcements in the form of values and personal commitments.

Reinforcing factors are those consequences of action that determine whether the actor receives positive (or negative) feedback and is supported socially or financially after it occurs. Reinforcing factors thus include social support, peer influences, and advice and feedback by healthcare providers, as well as a sense that the benefits of the action outweigh the costs. In consideration of the benefits (and costs), they also include physical consequences of behaviour, which may be separate from the social context. Examples include the feeling of well-being (or pain) caused by physical exercise and the alleviation of respiratory symptoms (or the experience of side effects) following the use of asthma medication, or gaining weight while quitting cigarettes.

Public health uses reinforcing factors such as denormalizing smoking in public places, social reinforcement with encouraging words in personal counselling, small-group health education sessions in which behaviour is publicly endorsed and praised, or mass media images of attractive role models with whom people wish to be associated by their own behaviour. No matter how effective these extrinsic reinforcements might be in the short term in strengthening a behavioural tendency, they must be internalized over time to become intrinsic motivation. Token rewards lead to token behaviour if the individuals do not replace them over time with the belief that the behaviour is intrinsically valuable because it accords with their own personal values (Green et al. 1986).

Table 2.10.2 gives examples of the more commonly identified influences on each of four most important behavioural risk factors. These behaviours interact with each other, such that changes in one influence predisposing, enabling, and reinforcing factors substitutes influences on others.

Table 2.10.2 Some known and suspected predisposing (a), enabling (b), and reinforcing (c) influences on four major behavioural risk factors

Cigarette smoking	Dietary practices	Alcohol use/abuse	Physical inactivity
• Knowledge of adverse health effects of smoking (a) • Attitudes about smoking (a) • Skills in smoking cessation/prevention (b) • Cigarette cost (b and c) • Availability of cigarettes (b) • Cigarette advertising (a) • Peer influences to smoke (c) • Social support for non-smoking (c) • Smoke-free policies in worksite (b and c) • Access to cessation services (b) • Attitude towards tobacco industry practices (a)	• Personal food preferences (a) • Cultural food preferences (a) • Perceived social acceptance of foods (a and c) • Social context of eating (b and c) • Availability and convenience of healthful foods (b) • Skills in menu planning (b) • Skills in food preparation (b) • Skills in food selection (b) • Food advertising (a and c) • Healthful options in vending machines (b) • Belief in personal susceptibility to risk factors (a)	• Expectations of alcohol effects (a) • Child of alcoholic (a) • Alternatives to alcohol (a and b) • Psychological stress (a, b, and c) • Low self-esteem (a) • Early drinking experience (c) • Heavy social drinking (c) • Parent and peer influences (c) • Alcohol advertising (a, c) • Cost of alcohol (b) • Availability of alcohol (b)	• Beliefs in physical activity benefits (a) • Attitudes towards physical activity (a) • Self-efficacy (a) • Resources, facilities for exercise (b) • Cost of exercise facilities (b) • Skills in relapse prevention (b) • Skills in goal setting (b) • Enjoyability of physical activity (c) • Family support (c) • Design of the built environment (b and c) • Belief in benefits of physical activity

Public health strategies to influence determinants of behaviour

Another chapter will deal with the full range of health promotion and health education strategies (see Chapter 6.4). The focus of this section is specifically on how the aspects of the environment discussed in the previous sections that shape health-related behaviour can be targeted for strategic intervention for public health purposes. Three types of strategies are used in public health to accomplish health promotion and disease prevention goals through behaviour change:

Educational strategies inform and educate the public about issues of concern, such as the dangers of drug misuse, the benefits of automobile restraints, or the relationship of maternal alcohol consumption to fetal alcohol syndrome.
Automatic-protective strategies are directed at controlling environmental variables, that minimize the need for individual decisions in structuring each behaviour, such as public health measures providing for milk pasteurization, water fluoridation, infant immunizations, and the burning or chemical killing of marijuana crops, but these often involve individual and group decisions and actions about which policies to support, since they limit degrees of freedom in choice of behavioural options.
Coercive strategies employ legal and other formal sanctions to control individual behaviour, such as required immunizations for school entry, mandatory tuberculosis testing of hospital employees, compulsory use of automobile restraints, and arrests for drug possession or use or for drunk driving.

Illustrative of successful public health measures reflecting this range of strategies directed at influencing health-related behaviours are the efforts to control tobacco consumption. Influencing tobacco-related knowledge and attitudes has been declared one of the great public health achievements of the twentieth century, at least in the United States (Centers for Disease Control 1999) and several other countries. Considering that these successes, as measured by the reductions in tobacco consumption behaviour, were achieved largely in the last third of the century, they represent both a remarkable turn-around of an epidemic of smoking behaviour that had increased inexorably through the first two-thirds of the century, and an inspiration for public health approaches to other health-related behaviours that now show similar epidemic trends. The application of the lessons from tobacco control to reversing, for example, the obesity epidemic through similar influences on dietary and physical activity behaviours has become a point of major public health debate in the early years of the new millennium (Mercer et al. 2005; Green et al. 2006; Eriksen et al. 2007; Institute of Medicine 2012).

Influences on smoking initiation and cessation are numerous, and many of them are also intertwined with diet, alcohol, and physical activity. Predisposing factors include attitudes about smoking and beliefs about and knowledge of the health effects of smoking. Enabling factors of access to

tobacco products and price are influential. The price elasticity has been documented at a 3 per cent decrease in tobacco consumption for every 10% increase in the price, and a greater relative decrease in youth, for whom disposable income is less (Ranson et al. 2002; Wilson et al. 2012). The influence of raising taxes on cigarettes, then, has been a major public health strategy with known effects on consumption. With the dedication of part of the tax revenues to the funding of comprehensive tobacco control programmes, some jurisdictions have achieved a doubling and even tripling of the rate of decline in per capita consumption compared with other jurisdictions in the same country (Mercer et al. 2005). But more powerful still are the cumulative reinforcing factors of growing social support and pressure for smoke-free environments as smoking becomes denormalized with the decline in prevalence rates and the legal restrictions on smoking in public places (Eriksen et al. 2007; Wilson et al. 2012).

Cigarette advertising and promotions by the tobacco industry have proved to be powerful negative predisposing and reinforcing influences on smoking behaviour that are highly adaptable to changing regulatory attempts to control their content and channels. Initial restrictions on US tobacco advertising in the broadcast media in the mid-1960s, for example, resulted in the tobacco industry voluntarily withdrawing from radio and television advertising, but adroitly using those resources from mass media to expand its advertising vastly on more targeted print media in magazines, billboards, and youth-oriented outlets. Sponsorship of sports and arts events and clubs, for example, provided a more targeted venue for reaching youth and other susceptible markets. Response of some jurisdictions in restricting these sponsorships has produced reductions in youth uptake of tobacco products (Hagmann 2002; Perez et al. 2012). Diversification of advertising to youth-oriented media and point-of-purchase settings such as stores near schools has resulted in increased restrictions in many jurisdictions. The restrictions have been largely disappointing, which is attributed to the agility of the industry in finding loopholes and ways to circumvent the new legal restrictions.

Attempts to control the determinants of tobacco consumption also illustrate an essential public health lesson in the importance of comprehensive programmes to affect the complex behaviours associated with chronic diseases (Centers for Disease Control and Prevention 1999, 2007). Comprehensive approaches have proved critical because:

No single intervention reaches all segments of susceptible people in a population (Green and Glasgow 2006).
No single intervention reaches different segments with the same degree of effectiveness (Warner 2011; Green 2014).
Different interventions are differentially effective in the different phases of change (Prochaska et al. 2002).
Different interventions variously influence the predisposing, enabling, and reinforcing determinants of behaviour in a population (Green et al. 2019).
This comprehensiveness lesson has been carried forward to public health efforts in diet, alcohol, and physical activity insofar as they have increasingly engaged multiple organizations in community coalitions and multiple sectors and national programmes to address the various determinants that extend beyond the purview of the medical and public health sectors at the local level. The complexity of these organizational and ecological layers and intersections of influence on both physical activity and food consumption have driven a concerted effort in the rush to find remedies for the obesity epidemic to include ecological models and systems models (Institute of Medicine 2012).

The promotion of physical activity or active living illustrates the lessons of comprehensiveness and multisector involvement in public health strategies to influence a complex behaviour. Increasing attention has been given in recent years to the built environment, including the density of housing, mixed-use neighbourhoods, and sidewalks that encourage walking to and from home for shopping, work, and recreation; provision of mass transit that also supports walking the distance to and from transit stops rather than driving to work and other destinations (Frank 2000; Sallis et al. 2012).

The recent growth of the active living field is an extension and integration of traditional public health approaches with more collaborative approaches involving sectors such as housing, parks and recreation, and transportation. It responds to the increasing recognition of the complexity of health risk behaviours related to chronic diseases and their numerous determinants. The performance of each behaviour is interwoven with or ecologically embedded in other behaviours, organizations, and ecologies (Ottoson et al. 2009).

Behaviour as determinant of environmental and genetic predispositions

Population behavioural and educational diagnoses enable public health to intervene strategically on the behaviour of populations. But health problems have other determinants in the environment and in genetics. Behaviour also can play a role in influencing those determinants.

The reciprocal influence of individual behaviour on environments

A fundamental precept of human ecology is the reciprocal determinism of behaviour and the environment (Green et al. 1996; Sallis et al. 2012). The literature on health promotion took a sharp turn away from behaviour in the 1980s to give attention to the policy and environmental determinants of health. This was partly in response to a period in which public health was perceived to have taken too much of a psychological approach to the determinants of health (Green 2006). As early as 1968, Edward S. Rogers had appealed to sociology for the assistance public health needed from the social sciences to address the ecological issues (Rogers 1968). Psychologists, however, were more available, at least in the United States, to step into the perceived social science void of public health and to take up the new professorships in public health. They brought an emphasis on testing theories of individual behavioural change. As the ecological imperative of multilevel interventions (individual, family, organizational, community, regional, national, and global) gained growing emphasis in public health (e.g. Kickbusch 1989; Green et al. 1996), a gradual turn to the study of behaviour-in-context gave reciprocal determinism a new lease on life in public health (Stoto et al. 1997; Institute of Medicine 2001, 2003) in the decade bridging the millennium. One theory of behavioural change that gained particular public health prominence in this era was Albert Bandura's social cognitive theory, with its emphasis on self-efficacy and individual agency in changing one's environment at the same time that it gave prominence to the social environment in shaping behaviour (Bandura 2004).

Some of the environmental determinants of health beyond the behavioural control of individuals nevertheless lend themselves to group political behaviour or collective action through community intervention. Communities, neighbourhoods, or special-interest (self-help) groups can organize, vote, lobby, boycott, and otherwise support or prevent some environmental changes. To varying degrees, individuals can avoid or limit

their exposure to environmental risks such as solar radiation, lead paint, and ambient smoke. In short, individual behaviour can be mobilized to influence the environment, so that individuals need not be seen only as passive objects of environmental influence.

The projected but still limited mobilization of behaviour to influence genetics

The Human Genome Project and the explosion of research on human genetics have raised very hopeful scenarios of ‘precision medicine’, in which individuals could know more precisely their genetic risk of certain diseases, causes of death, and most effective treatments (National Research Council 2011). The usual assumptions are that such information could be made readily available to individuals, and that having such information would be considerably more compelling in motivating behaviour than the usual statistical risk of groups of people without the personalized association with the individual in question.

The first assumption remains to be supported by true evidence of effectiveness. For example, in about 30% of women with breast cancer, overexpression of a protein called HER2/neu is associated with a worse prognosis and in such women the drug trastuzumab is especially effective. The US Food and Drug Administration approved the drug and a test for HER2/neu for use in women with metastatic breast cancer in 1998 and more recently for women with early stage breast cancer (Hortobagyi 2005; Braga et al. 2006). The co-development and approval of the drug and test is considered one of the real successes of the application of genetics to modern medical practice and among the best examples of ‘precision medicine’. One might think the story is complete. However, although this information about the efficacy and availability of the test and the drug was published and promulgated by commercial backers, the behaviour of clinicians and their patients has been a more complicated matter. There is little known about how many women have access to testing and treatment. The costs of both are high and cost-effectiveness issues remain a challenge. Also how best to administer the test has not been resolved (e.g. timing) and there are reports of an increased risk of heart failure, the effect of which on acceptance is not known.

The second assumption, that having such information would motivate more concerted effort to change one's behaviour, is only partially supported by: (1) the logic and evidence from other areas of health counselling and communications that more personally tailored health information based on the individual's own family history or biological risk information adds motivational value to the experience with health advice that is based on more generic information (Kreuter et al. 2005); (2) limited direct evidence from the few instances in which such genetic information has been used to counsel individual behavioural choices of action. The latter is illustrated by the examples in the previous paragraph and those from prenatal testing and counselling for birth defects. However, a meta-analysis of 21 controlled trials showed that while genetic counselling improved knowledge of cancer genetics, it did not increase the level of perceived risk and few studies examined cancer surveillance behaviours (Braithwaite et al. 2006).

Public health faces two major limiting factors in pursuing this pathway of behaviour influencing health through genetic determinants: (1) the limited influence of the genes so far implicated in specific mortality or morbidity outcomes, and their interactions with the environment, and (2) the ethics of offering such information to the individual with anything more than a cautionary note of possible relevance to their reproductive decisions or their behavioural choices. The first is a limit that could be partially overcome with further breakthroughs in the human genomics research. But apart from some prenatal tests for genetic defects in the foetus, most of the other genetic markers associated with predispositions to illnesses or premature mortality are highly interactive with other genes and the environment (Kahan and Cheskin 2014, p. 237). Therefore, any course of action recommended to the individual remains probabilistic in its assurance of a health benefit. In combination with the other risk factors that can be more readily identified, the addition of personalized genetic information might raise the probabilities sufficiently to help the individual reach a tipping point in motivation to take action on complex health-related behaviours. But whether it really adds motivational value to what could be similarly known from a good family history has yet to be demonstrated.

The other limiting factors for this behaviour–genetic pathway as a public health consideration are the ethical complications that arise with the technology and the information. The concern, as in other screening technologies, with false-positive results can be multiplied in their ethical

considerations for genetic information on individuals. The usual issues of protecting the privacy of such information and the potential discrimination in hiring, placement, retention, and promotion of individuals with known genetic predispositions will continue to be debated before the 'precision medicine' potential of expanding the behaviour–genetic pathway can be pursued as public health policy. Meanwhile, private medicine and industry (e.g. 23andMe) is opening opportunities for individuals to explore this option in structuring their behavioural response to personal genetic information, as research on the behavioural implications mounts with three priorities: '(1) improving the public's genetic literacy in order to enhance consumer skills; (2) gauging whether genomic information improves risk communication and adoption of healthier behaviours more than current approaches; and (3) exploring whether genomic discovery in concert with emerging technologies can elucidate new behavioural intervention targets' (McBride et al. 2010). Chapter 8.19 addresses human genetics more thoroughly.

The interaction of socioeconomic status, environments, and behaviour

Of all the interactions in the association of behaviour and health, none is more pervasive, consistent, and robust than that of socioeconomic status (SES). The relationship between SES and measures of health or mortality is shown in other chapters to be a gradient rather than a threshold effect, though threshold effects (or points of diminishing returns) are sometimes found beyond which income or other SES indicators have no further beneficial effects (e.g. Finch 2003). Those at the top of the SES hierarchy usually have better health and lower mortality rates than those just below them who are themselves better off than the others below them, and so on down to those in poverty at the very bottom. The gradient adheres whether the SES measure is education, income, occupational status, or place of residence. The gradient globally is anchored at the lowest end by the poorest developing countries. These historical associations between health behaviours and SES have been confounded in the more recent tracking of obesity, physical activity, and food consumption. The more sedentary work and modes of travel of a majority of white collar workers blur the

educational, income, and occupational correlations with physical activity (e.g. Canadian Institute for Health Information 2006). In Canada, for example, 'of the demographic variables examined, income, occupation, and employment status were unrelated to obesity, while education was negatively associated with the prevalence of obesity' (Raine 2004, p. 6).

Some 767 million people globally in 2013 lived in extreme poverty on an income of just US $1.90 a day, of whom half live in sub-Saharan Africa (World Bank 2018). Many of the poor lack access to basic health services including sanitation and clean water and are at exaggerated risks for many of the leading causes of death in those countries. The gradients are further complicated by the varied statistical interactions of gender, racial and ethnic discrimination with income, education, and occupation—the usual metrics of SES—in different countries.

While SES has been found to directly affect health through mechanisms such as material well-being and psychosocial stress, this chapter focuses on the role of SES on behaviour (Lynch and Kaplan 1997; Wilkinson and Marmot 1998; Seeman et al. 2010). The question here is how the mortality and morbidity gradients with socioeconomic status might operate through health-related behaviours, cultures, and environments, whether operating through increased access to resources and material wealth or through lower psychosocial stress. Earlier discussion in this chapter suggest mechanisms by which the pervasive SES gradient influences health, and ways in which the behavioural pathway can be made more protective or preventive.

SES as a predisposing determinant of behaviour

The ecological perspective on SES as a determinant of behaviour related to health would suggest first that environments shape behaviour from early childhood onward. Shaping behaviour in the first instance (rather than enabling it in the second or reinforcing it in the third) qualifies this environmental influence as a predisposing factor. Homes, neighbourhoods, towns, cities, regions, and whole countries with their variable physical, social, economic, and cultural environments differ in relation to SES measured at individual, family, neighbourhood, and other geographic levels. Once the measures of SES and health or mortality are aggregated above the individual level, their relationships constitute ecological correlations. Studies have examined the ecological relationship between mortality rates and

various indicators of social inequalities in geographical areas varying in size from metropolitan areas (Lynch et al. 1998) to whole countries (Wilkinson and Marmot 1998). These studies showed that those areas where inequalities between those at the top of the hierarchy and those at the bottom were the largest were also those in which the mortality gradient was the strongest (Wilkinson 1996). Similar findings were found with other indicators of social inequities such as differences in social capital (Kawachi et al. 1997). Health disparities between socioeconomic groups appear from Canadian data to increase with age across the lifespan, which supports the notion of a cumulative effect over time of the health- and mortality–SES gradient (e.g. Prus 2007).

One implication of this relative deprivation dimension of the SES–health gradient is that perception of one's status relative to others de-motivates or discourages one's efforts to take greater control over the behavioural and environmental determinants of one's health. Whether consciously discouraged or unconsciously conditioned by repeated confrontations with inequalities and inequities that conspire against one's efforts, the hypothesis is that disparities make those exposed to relative deprivation less predisposed or motivated to take preventive and healthcare actions. Two specific mechanisms have been suggested for this de-motivation or lack of predisposition to undertake behaviour. One is a chronic pessimism that has been found in adolescent children of lower SES parents, and that pessimism was associated with stress (Finkelstein et al. 2007). The other possibly related mechanism is the theoretical construct of 'self-efficacy' and diminished stress, widely measured in association with social cognitive theory applications in health behaviour research (Bandura 2004; Jang and Yoo 2012).

SES as an enabling determinant of behaviour

Socioeconomic standing also confers capabilities and resources that enable the predisposed behaviours to be carried out, for better or for worse. With higher standing come more resources and the associated education and training that endow individuals, families, groups, and communities with enabling judgements, resources, and skills. No matter how motivated people may be by their predisposing factors, they may not have the income and other resources, including accessible and affordable services within reach of

their residences or workplaces, to be able to carry out the behaviour without great sacrifice and inconvenience. But environmental variables of accessible fruit and vegetable outlets in local neighbourhoods, for example, only partially explain or mediate the relationship between SES and fruit or vegetable consumption (Ball et al. 2006). The ‘food deserts’ of poor access to fruits and vegetables in neighbourhood stores of poor areas are compounded by the high accessibility of the ‘food swamps’ of fast food restaurants with their calorie-dense menus (Fielding and Simon 2011).

The educational enabling influence of SES on behaviour

Among the SES indicators, education has for decades demonstrated the strongest association with most health behaviour measures (Green 1970; Metcalf et al. 2007), and this association has been found to have a major part of its essence in health literacy (e.g. Curtis et al. 2012). It also stands out among the indicators of inequities in confirming the relative deprivation hypothesis (Kunst and Mackenbach 1994). Education can be viewed as a proxy for a variety of predisposing and enabling factors in explaining the causes of behavioural determinants as mediators of at least part of the SES–health gradient. Prominent among these are optimism (a predisposing factor) and education as an enabling or coping resource (Finkelstein et al. 2007), with the knowledge, attitudes, and skills that come with years of schooling.

The proportion of people in Canada who are smokers is double in people with elementary or lower education, compared with people with university degrees (Adams 1993; Health and Welfare Canada et al. 1993). This spread in proportions of smokers was greater for the highest and lowest education categories than for the highest and lowest income or occupational status categories (Pederson 1993). Data from the major US community trials in cardiovascular disease prevention showed that the dramatic drop in smoking prevalence over the 1980s was more pronounced for people with higher education compared with people with less education (Winkleby et al. 1992a; Luepker et al. 1993). The same trend was observed in Canada for the period 1985–1991 (Millar and Stephens 1993).

SES as a reinforcing determinant of behaviour

A behaviour that is predisposed and enabled might still fail to persist beyond a trial stage of acting if it fails to produce satisfying results. Satisfaction comes from various sources that can have the effect of reinforcing behaviour. SES can contribute to the availability of reinforcements by putting people into association with other people and environments that are more likely to produce satisfaction with behaviours. Two examples follow.

The ‘status identity factor’ and social norms

The social-normative theory underlying the notion of SES functioning like a reinforcing factor would predict that people will identify with a place in the social hierarchy that they can justify on the basis of their highest achievement. Unlike the usual measure of SES produced by averaging standardized or weighted measures of education, income, and occupation, one hypothesis derived from social reinforcement theory was that people will aspire to and adhere to that norm of a particular behaviour associated with their highest measure on the gradient of SES. For example, a person who is relatively high on education, but of moderate income and occupational status, would tend to adhere to the behavioural norms of the highest, rather than the average, of the person’s three status scores. The hypothesis was tested in a California state-wide sample of mothers of children under 5 years, demonstrating that the immunization status of the children and five other measures of early childhood care followed a gradient with SES, but that the best predictor of the mother’s behaviour on these five measures was her highest standardized SES among income, education, and occupation, not the average. This inferred ‘status identity’ of the mothers provided a basis for linking the psychological phenomena of identification and role modelling with the sociological concept of normative influence (Green 1970).

Denormalizing behaviour

In retrospect, one of the most important elements of the tobacco control success of the last third of the twentieth century in the United States and Canada was the ‘denormalization’ of smoking behaviour in public places (Eriksen et al. 2007; Rogers 2010; Livingood et al. 2011). What had been a normative behaviour of smoking in the workplace and in restaurants, meeting rooms, and other public places became increasingly unacceptable,

first by legal restrictions, then by social norms, by which the growing majority of non-smokers expected and even insisted on smoke-free environments. The combination of new smoke-free or ‘clean air’ ordinances and by-laws with mass media emphasizing the carcinogenic properties of second-hand smoke and the rights of non-smokers to be spared the exposure to this carcinogen resulted in a dramatic drop in this public behaviour. It was during this period of the 30-year decline in smoking that the rate of decline accelerated most dramatically. One reason for the importance of this element of the tobacco control campaigns was that the passage and enforcement of policies restricting a personal behaviour faced strong opposition as long as it was perceived by the public to be a matter of individual rights and the threat to be only to the person’s own health. When the threat is seen to be to other people’s health, especially to the health of children, the support of passage and enforcement of the laws and regulations grows. Other public health campaigns are attempting to model this experience, which builds on the social responsibility notions associated with communicable diseases of the past, but with most of the chronic disease-related behaviours, such as overeating and sedentary living, it has been more complicated to relate the normative behaviour of individuals to the health of others.

The interaction of socioeconomic status, gender, and behaviour

Men’s and women’s relative risk of disease or death in relation to specific behavioural risk factors such as smoking are generally similar (e.g. Oliveira et al. 2007), but their experiences with health differ markedly (Chapman Walsh et al. 1995). These differences cannot be attributed solely to biological determinants related to sexual differentiation (Krieger et al. 1993). The social construct of gender, as opposed to the biological categories of sex, was conceptualized to refer to cultural and social conventions, roles, and behaviours assigned to men and women (Krieger 1996). These in turn shape the social, political, cultural, and economic circumstances experienced by men and women. Gender thus attempts to capture this differential experience that men and women have with their environment and the possibilities and constraints associated with these differences (Potvin and Frohlich 1998). Some of these constraints and possibilities are interacting with the living conditions associated with SES to shape the health of people (Wilkinson and Pickett 2008).

The correlation of SES with health appears stronger for men than for women; the SES–health gradient is steeper for men (Mustard and Etches 2003). The gender interactions with SES and health have been variously attributed to differential occupational experiences (e.g. Ross and Bird 1994), marital experiences (Koskinen and Martelin 1994), and degree of emancipation of women (Kawachi et al. 1999). These and other possible explanations generally require assumptions of behavioural mediators. Such mediators are as likely to be 'health-related' behaviour (e.g. sedentary living or food consumption patterns) as 'health-directed' behaviour (e.g. exercise or high-fibre diet). This distinction (Green and Kreuter 2005) recognizes the centrality of behaviour in the causal chains even when (perhaps especially when) it is not consciously health-*directed* behaviour.

Relationships among health-related behaviours

The interplay among habitual behavioural patterns and the socioeconomic and cultural conditions reviewed in the last half of this chapter leads one to put into a broader context the reductionist examinations, presented in the first half, of specific behaviours as they relate to health, disease, and mortality. The dynamic relationships among the specific measures create a complex system of social, economic, cultural, and behavioural factors, interwoven with disease risk factors and health status, and influenced by the healthcare and physical environments. There is little evidence supporting a one-dimensional concept of health-related behaviours (Calnan 1994) or a uniform 'healthy lifestyle'. It supports, instead, the reciprocal and ecological system of relationships laid out in the various sections of this paper, showing behaviour as both a product and an active ingredient in the mix of cultural, socioeconomic, and environmental conditions affecting individual and population health.

Conclusion

Behaviour is an inescapable link in the chain of causation between most environmental and genetic determinants and the health outcomes in which they are implicated. Some toxins and infectious environmental agents can affect health directly without behaviour as a mediator, but even these *can* be

mediated by individual action to avoid exposures, and collective behaviour of groups or communities to protect themselves.

The *social* environment presents a further complexity in the mediating and moderating of behaviour and environment in their determination of population health. Most health-related behaviour occurs in the context of the social environment, so it involves the behaviour of other people as well as that of the person whose health is in question. The individuals are acting upon, and in reaction to, each other as their health outcomes are being shaped by their actions. This reciprocal determinism of behaviour and the social environment applies as well to the physical environment and the genetic determinants of health. These interactions make up the ecology of health, and call upon public health to take an ecological approach to the management of population health.

One way to structure the ecological approach to the planning of public health programmes in which behaviour change has a role is to examine the factors that influence behaviour in three categories of determinants: predisposing factors, enabling factors, and reinforcing factors. These roughly correspond to strategies, respectively, that would use: (1) direct communications to influence the knowledge, attitudes, beliefs, and perceptions of the population concerning the behaviour–health relationship; (2) legal, engineering, financial, organizational levers, and resource development that would enable, restrain, or prohibit the behaviour; and (3) indirect communications through social organizations, parents, peers, employers, and others who control rewards and approval that would reinforce behaviour. By combining public health strategies directed at these three categories of determinants (predisposing, enabling, and reinforcing factors) the strategies will be comprehensive in their coverage and impact.

All of what has been understood as determinants of the health behaviour of individuals applies with some variation to the behaviour of health professionals, other practitioners and policymakers who could serve as channels through which to reach individuals, groups, and whole populations to influence their health behaviour. The actions of all of these categories of individuals, as well as their organizations, can be analysed in relation to the factors that predispose, enable, and reinforce their actions, and these analyses can point, in turn, to the development of strategies to change those behaviours.

ACKNOWLEDGEMENTS

We are indebted to Denise Simons-Morton, MD, PhD, and Louise Potvin, PhD, co-authors of this chapter respectively in its first and second editions, for remnants of their earlier contributions that may remain in this fourth revision.

2.11

How access to healthcare affects population health

Yvonne Inall, Rachel Lamdin Hunter, Stephen Leeder, and Angela Beaton

Introduction

This chapter explores access to healthcare—the timely availability of professional health services to prevent, diagnose, and treat illnesses and to preserve or improve the health of individuals—and its consequences. The interplay between access to care and population health has been seen dramatically in the Covid-19 pandemic. Systems of care have been stressed to breaking point with loss of life and failure of confidence in the public health system.

Access varies among and within countries. The challenge of providing access in relation to both communicable and non-communicable diseases is formidable (The Economist Intelligence Unit 2017).

Providing access is complex. Which groups or organizations are responsible for provision (the enablers), and how might access be financed? More people are living longer, with long-term comorbidities. The disease burden in developing countries is shifting. By 2020, non-communicable diseases are likely to account for approximately 70% of preventable, premature deaths (WHO 2018). How much care should be provided, and at what level? Is access confined to a minimum set of services or does it include more expensive and innovative treatments?

Countries and their governments vary in their political and social attitudes to access. Those with a strong social welfare agenda might focus attention and budgets on social factors such as education and social welfare; these not only determine health, but also access to care. Others, regarding healthcare as the individual's concern, might give these factors less weight. These variations in response have been apparent in the Covid-19 pandemic.

Despite this complexity and much national variation, access depends, in general, most often on good primary healthcare, public investment, and political will, availability of data to guide resourcing decisions, and the development of a well-trained, integrated workforce with appropriate supporting infrastructure.

Definitions

Primary healthcare

Our working definition of primary healthcare is ‘the first point of contact an individual has with the healthcare system’. It might be provided by a physician, community nurse, or by other clinical or non-clinical allied health professionals.

Effective primary healthcare provides accessible, comprehensive, culturally acceptable, community-based services to meet the health needs of individuals throughout their life-course—from family planning and infant immunizations to management of the comorbidities of the elderly and to palliative care. It also serves as the entry point for care in manging endemic and epidemic infectious disease, such as Covid-19, including vaccination.

The watershed WHO Conference on Primary Health Care held at Alma-Ata in the then USSR in 1978 defined primary health as the first level of contact with a healthcare system:

> Essential healthcare based on practical, scientifically sound and socially acceptable methods and technology made universally accessible to individuals and families in the community through their full participation and at a cost that the community and country can afford to maintain at every stage of their development in the spirit of self-reliance and self-determination. It forms an integral part both of the country’s health system, of which it is the central function and main focus, and of the overall social and economic development of the community. It is the first level of contact of individuals, the family and community with the national health system bringing health care as close as possible to where people live and work, and constitutes the first element of a continuing health care process. (WHO 1978)

The breadth of services and professions which fall within the definition means that the nature of the services might vary substantially between and within countries. This variability creates major challenges for data collection and assessment, financing, policy development, and decision-making.

Guiding principles in primary healthcare

Convened by Dr Halfdan Mahler, then Director-General of the World Health Organization, the Alma-Ata conference was a response to the social target set the previous year at the Thirteenth World Health Assembly, calling for ‘the attainment of all citizens of the world of a level of health that will permit them to lead a socially and economically productive life’ by the year 2000 (WHO 1988). Representatives from 134 UN member states and 67 UN organizations attended this seminal meeting. The objective was to agree on a set of principles for primary healthcare, to be endorsed by WHO and UNICEF. The principles agreed at Alma-Ata included:

accessibility and fairness;
relevance of the service to the needs of the population;
cost effective use of technology;
integration between primary, secondary, and tertiary care;
encouragement of self-care;
community involvement in the planning and provision of health services;
collaboration between the health and other sectors in addressing underlying causes of ill-health; and
redistribution of healthcare resources to primary healthcare, in rural and economically disadvantaged areas.

These aspirations were widely endorsed (Bhutta et al. 2018), but 40 years after Alma-Ata, primary healthcare remains inaccessible to at least 400 million people. The reasons include:

a lack (or misdirection) of public investment;
provision of inappropriate service models; and
disproportionate concentration of workers and resources in urban areas.

Secondary healthcare

We define secondary healthcare as care by specialists to whom patients are referred by a primary health carer. Depending on the field of specialist practice, it might take place in a hospital, a stand-alone purpose-built, or modified facility, or the specialist’s consulting rooms. Obtaining secondary

care can be challenging, depending on geography, transport, and funding (Araujo et al. 2018).

The relationship between primary and secondary care providers operates both ways. Patients might not only be referred to secondary care providers by primary health carers, but secondary healthcare providers might refer patients to (or expect them to utilize) primary healthcare services following discharge from hospital, or as part of a coordinated care plan, drawing upon both primary and secondary services.

A study of the relationship between primary and secondary care provision in Norway showed that primary healthcare workers felt that hospital-based carers 'do not speak [our] language' (Araujo et al. 2018). Breakdowns in communication were common. Primary and secondary carers had different ways of understanding patients' needs. Efforts to improve coordination revealed problems relating to information technology, municipal, hospital and fiscal policy, and resistance to cultural change, all of which adversely affected attempts at harmonization.

Equity

Equity in healthcare can be evaluated in several ways (Table 2.11.1). An important distinction, attributed to Aristotle, is between horizontal and vertical (Gillon 2005). Horizontal equity requires that equals should be treated in proportion to their equality, while vertical equity requires that unequals should be treated in proportion to their inequality.

In vertical equity, those with the greatest needs receive the greatest attention. Horizontal inequality, like inequality in income or health, is often measured using Gini-like metrics known as concentration indices (Mackenbach and Kunst 1997). In reality, different groups in a population have different needs and require appropriately differentiated services; for example, the healthcare needs of indigenous Australians, whose life expectancy at birth is some 10.6 years less than that of the general population (AIHW 2018). Mooney (1996) has asked about a fair distribution of health resources, given this large difference in health status?

There is little consensus on the vertical dimension of equity. Marginalized groups, such as indigenous populations, new migrants, immigrants who have not mastered the language of the host country, poorly educated people, the disabled, homeless, or prisoners might be regarded as

‘hard to reach’ or at least ‘underserved’ by standard services. In such cases, there might be a case for targeted services. There is, however, a concern that such targeted services can be seen as ‘poor services for poor people’, with the attached stigma. More generally, there is an increasing emphasis on designing local services to meet locally expressed needs, leading to greater variation in organization and delivery, contrasting with the uniform approach implied by the pursuit of horizontal equity.

In the United Kingdom, the tension between these two dimensions of equity was addressed through the introduction of national level service specifications, which accommodated local discretion in implementation. However, the National Health Service (NHS) has come under increasing pressure resulting from austerity economic cuts to funding, staffing shortages, an ageing UK population and increasing social inequality (Iacobucci 2019).

Ivan Illich, a radical critic of Medicine, claimed, ‘a vast amount of contemporary care is incidental to the curing of disease, but the damage done by medicine to the health of individuals and populations is very significant’ (Illich 1976). He acknowledged that Medicine, using vaccinations and antimicrobial drugs, aids in preventing and curing infectious diseases, but he argued that big reductions in mortality from infectious diseases in high-income countries had already occurred before these technologies became available. In his opinion, treatment of non-communicable diseases, such as cancer and cardiovascular disease, was of negligible benefit and indeed might cause considerable harm.

Richard Smith, former editor of *The British Medical Journal*, an iconoclast and a fan of Illich, put it this way:

> Health, argues Illich, is the capacity to cope with the human reality of death, pain, and sickness. Technology can help, but modern medicine has gone too far—launching into a godlike battle to eradicate death, pain, and sickness. In doing so, it turns people into consumers or objects, destroying their capacity for health.
>
> Limits to medicine. Medical nemesis: the expropriation of health. R Smith http://dx.doi.org/10.1136/jech.57.12.928

Illich’s opinion was supported by the controversial English physician, historian, and epidemiologist Thomas McKeown, in his analysis of historical trends in mortality in Britain (McKeown 1979). This analysis identified the limited role of Medicine as a past determinant of health. For example, relative reductions in mortality between 1881 and 1950 ranged

from 30-fold for tuberculosis, 20-fold for digestive diseases, and 15-fold for respiratory diseases (ONS 1998). Most of these reductions occurred before the widespread use, after 1945, of disease-specific antimicrobial treatment.

Archie Cochrane, famous today for his advocacy of the use of the randomized trial (RCT) in assessing the effectiveness of therapy, developed a somewhat similar argument in *Effectiveness and Efficiency* (Cochrane 1972). Cochrane advocated the now generally accepted view that, if at all possible, all care interventions should be tested in RCTs, and that the results of all such trials should be systematically collected, analysed, and implemented in clinical practice. Only recently, with the advent of genetic-based 'precision medicine', has a serious advance been made over RCTs in assessing the utility of proposed new therapies. Precision medicine, unlike RCTs, is specific to individuals.

Table 2.11.1 Aspects of equity in health and healthcare

Term	Meaning
Equity	Fairness, or justice, in respect of treatment of different individuals or groups (Last 2007)
Horizontal equity	The extent to which equals are treated in proportion to their equality
Vertical equity	The extent to which unequals are treated in proportion to their inequality
Equity in financial contribution	The extent to which individual or household payments for care or health insurance are consistent with their capacity to pay
Equity in access to healthcare	The extent to which there is a fair distribution of access to healthcare in relation to need
Equity in health	The extent to which there is a fair or just distribution of opportunities for health among individuals and groups in a population
Effective coverage	The proportion of the population in need of an intervention that has received it (Shengelia et al. 2005)

Access to primary healthcare

In general terms, ‘access to healthcare’ is said to exist when individuals or families can physically get to the services they need to treat illness or to maintain health (Gulliford et al. 2002). An ongoing debate seeks to distinguish access from use of services. At the simplest level, having access might be assessed in terms of the ready availability of services (Table 2.11.2).

Obstacles to use include cost; physical barriers, including distance or difficulties of travel; personal barriers, when services are not felt culturally appropriate, socially acceptable, or not consistent with personal beliefs; or organizational barriers, such as difficulties obtaining a consultation, or delays because of waiting lists or the limited capacity of services (Aday and Anderson 1981; Pechansky and Thomas 1981). Utilization offers benefit only when effective care is relevant to needs (Table 2.11.2).

‘Access’ has recently been reappraised. It is proposed that access be understood in terms of individuals’ ‘candidacy’, namely their eligibility for healthcare (Dixon-Woods et al. 2006). Candidacy is defined both by individuals’ perceptions of their own concerns, as well as by health providers’ views of the appropriateness of their services to meet those concerns. In short, ‘access’ is meaningful when a person perceives a need and care is available.

Table 2.11.2 Dimensions of access to healthcare

Dimension of access	Meaning	Potential indicators
Availability	Whether or not there is an adequate supply of health services in an area	• Number of physicians or nurses per 1,000 population • Number of hospital beds per 1,000 population • Distance to nearest primary healthcare provider • Distance to nearest hospital
Utilization	Whether or not health services are utilized	• Primary healthcare consultations per l,000 population • Hospital admissions per 1,000 population
Relevance to need	Whether or not appropriate services are received by the people who need them	• Proportion of births attended by a trained healthcare professional • Proportion of individuals with known hypertension who are being treated
Outcomes	Whether achievable health outcomes are realized	• Maternal mortality rates are improved • Mortality rate from appendicitis is improved

Access to secondary healthcare

No matter how enthusiastically primary healthcare is developed and made accessible, the range of care provided stops short of major surgery, complex obstetrics, intensive medical care, sophisticated rehabilitation services, and long-term accommodation-based care.

In many low-resource settings, where community primary healthcare is rudimentary and where access to quality care is limited, the emergency departments of hospitals overflow with patients who might otherwise be cared for in primary healthcare.

At any of these institutions in resource-poor countries, we find mothers with sick (or very sick) children. They might have travelled days from remote villages to urban hospitals. The hospital becomes a *de facto* primary health carer. Nor is this phenomenon unique to low income countries. In resource-rich countries, care given to patients with serious and continuing illnesses is being reviewed to see if it could be given more efficiently through primary healthcare, especially when the services in both settings are linked and managed as a unit. Treatment for such patients is judged to be inappropriate when they receive expensive hospital care as a substitute for primary healthcare. There is no simple answer: primary healthcare services are increasingly limited to daytime working hours. At other times, the emergency department can, by default, offer primary healthcare.

Changing global and community disease burdens

The health gain of resource-rich countries in the twentieth century is well documented. A snapshot of the interval between the Second World War and now would also show improvements in health outcomes in developing countries, in parallel with increased education, sanitation initiatives, and improved local oversight of public health (Bollyky 2018). These improvements were closely related to rising prosperity and urban development. With money to spend, many such governments invested in potable water and in sewerage disposal. In turn, a healthier workforce contributed to prosperity.

A new set of problems has come with these advances. Chronic illnesses, once the scourge of advanced nations, are now prevalent in low- and middle-income countries. This reflects changes in food supply (including a greater proportion of highly processed foods), increasing availability of tobacco, and housing shortages. Many less economically developed nations face a loss of productive workforce in middle age due to chronic non-communicable diseases such as diabetes and cardiovascular diseases. It has been projected that, by 2040, 80% of premature deaths and disability in developing countries will be caused by heart disease, cancer, and other non-communicable diseases (Bollyky 2018).

In low- and middle-income economies, healthcare expenditure per capita remains relatively low and much chronic illness is untreated. Many less

developed nations spend about US$30 per person annually on healthcare, contrasted with US$5,400 in the United States and US$3,800 in the United Kingdom (Bollyky 2018). The opportunities for primary and secondary prevention through primary healthcare are often lost.

This change in the pattern of illness has slowly been recognized. The shift in funding away from preventing and treating communicable diseases to treating and managing the growing burden of non-communicable diseases (NCDs) is also noteworthy. Initiatives, like the Global Alliance Against Chronic Disease, are addressing the threats posed by NCDs. This body has 'arranged three of its four funding rounds by disease' (Fairall et al. 2018). But, as has been seen with efforts to control HIV, the difficulties imposed by health systems which do not integrate care for the whole individual can be almost as troublesome as the underlying disease. In the case of NCDs, the usual pattern is of an individual having multiple disorders (diabetes, heart, and lung disease, for example) which need linked care. Ideally, services should respond to multimorbidity rather than to individual diseases.

Citizens' 'right to healthcare'

Does any individual (or community) have a 'right to healthcare' or a right to access to care? Answers to this question are generally approached from either a utilitarian or human rights-based viewpoint. Another, objectivist view, sees healthcare as a commodity, to be bought or sold in an open market. This section will consider these different perspectives in the context of access to healthcare.

Human-rights-based approaches to a right to healthcare draw on two core documents: the Universal Declaration of Human Rights (UDHR) and the International Covenant on Economic, Social, and Cultural Rights (ICESCR). Rights to medical care are recognized under Article 25 of the UDHR:

> Everyone has the right to a standard of living adequate for the health and well-being of himself and of his family, including food, clothing, housing and medical care and necessary social services, and the right to security in the event of unemployment, sickness, disability, widowhood, old age or other lack of livelihood in circumstances beyond his control. (UN 2007)

The UDHR was adopted by the UN General Assembly in 1948, in the wake of the atrocities perpetrated during the Second World War. It is not a legally binding document, although it is generally accepted as holding status as customary international law, which is, regrettably, hard, if not impossible, to enforce. Enforcement is generally limited to violations linked to war and armed conflict (Gunning 1991; Henckaerts 2005).

Article 25 ties health and medical care directly to living standards and social services, welfare, and security, but without explicitly stating which governing entity should be responsible for funding and provision.

The International Covenant on Economic, Social, and Cultural Rights (ICESCR adopted by the UN General Assembly in 1966, and in force since 1976) expands upon the UDHR, requiring party states to 'recognize the right of everyone to the enjoyment of the highest attainable standard of physical and mental health' and to create 'conditions which would assure all medical services and medical attention in the event of sickness' (Office of the High Commissioner for Human Rights 2007); see also Chapter 3.3).

Unlike the UDHR, the ICESCR is a 'binding treaty', which, as of December 2018, has been ratified by 169 member nations (United Nations Human Rights, Office of the High Commissioner n.d.). Four nations, including the United States of America, have signed (but not ratified) the treaty. States party to the treaty have agreed to submit a compliance report to the ICESCR 5-yearly. Alleged violations might be referred to the ICESCR committee for investigation. However, agreement on how violations should be recognized or quantified is lacking, and enforcement is non-existent (Kalantry et al. 2010).

Taken together, the UDHR and ICECSR do not guarantee access to necessary services for every individual but, as statements of political and social *intent*, they offer an important degree of hoped-for protection for marginalized and vulnerable groups and individuals. There can, of course, be no guarantee of limitless care for any individual, nor does the resolution overcome the tyranny of distance where rural dwellers cannot access health services in the big cities. But the ICECSR places responsibility on governments to facilitate the healthcare of their citizens (discussed further in Section E). Ultimately, however, human rights, including the 'right to healthcare', are weakly protected at the international level.

Human rights-based approaches to access to healthcare link to concepts of equity and draw upon social contract theory and theories of ethics. These

approaches favour a just or equitable distribution of healthcare over the maximization of potential health gains for a favoured minority.

American moral and political philosopher John Rawls's theory of justice and fairness, proposes that a just society will be arranged so as to achieve fair equality of *opportunity* (Rawls 2007) not equality of *achievement* (for example, equal health outcomes from a particular treatment, which can never be guaranteed). Although saying little about health, Rawls envisioned his theory of justice as an extension of the social contract, as understood by Locke, Rousseau, and Kant (Rawls 2007).

Norman Daniels, an eminent American political philosopher and philosopher of science, has been more explicitly concerned with health than was Rawls (Daniels 2008). He argues that health is an important determinant of the extent of an individual's opportunities and that it therefore requires careful consideration if one wishes to establish a fair society. From Rawls and Daniels, equity stands out as a major 'ethical value', one which healthcare services should strive to promote (Braveman et al. 2001).

Cruess and Cruess, an orthopaedic surgeon and an endocrinologist at Canada's McGill University, respectively, have written extensively on medical professionalism, acknowledge that the relationship between the medical profession and the social contract remains poorly defined, emphasizing that 'the social contract between medicine and society differ between countries, being influenced by cultural, economic, and political factors' (Cruess and Cruess 2008).

In direct contrast to rights-based and social contract theory approaches to healthcare stands the objectivist position in which healthcare is not a 'right', but rather a 'service' offered by trained professionals. Rather than focussing on the 'rights' of the recipient of care, this approach considers the 'rights' of those who provide care. In this approach, healthcare is a commodity provided by trained persons who can expect remuneration and respect for their services, and who have the right to practise their profession where and when it is legal to do so. They also are entitled to withhold those services. They have the same entrepreneurial legal rights as any non-medical professional.

This objectivist approach to healthcare resonates especially in the United States, where it was clearly articulated by Robert Sade, an American surgeon and bioethicist, in the *New England Journal of Medicine* in 1971

(Sade 1971). Sade argued ‘the concept of medical care as a right of the patient entails the use or threat of violence against physicians [by the state]’. In Sade’s view, the rights of the physician to remuneration for service, and freedom to choose to whom to provide it, exceed the individual’s right to care. Gaffney describes this contrast as the ‘rights-commodity dialectic’, drawing on Gøsta Esping-Andersen’s arguments around the de-commodification of welfare services, facilitating subsistence without reliance on markets (Esping-Andersen 1990; Gaffney 2018). Sade came to describe this same contrast as one between ‘central planning’ and the ‘free market’, driven respectively by beliefs that ‘healthcare is an entitlement that must be provided by society and that obtaining healthcare is the responsibility of individuals’ (Sade 2012).

Adam Gaffney, an instructor in Medicine at Harvard Medical School and a pulmonary and critical care doctor at the Cambridge Health Alliance, is president of the advocacy organization Physicians for a National Health Program. Writing about the history of healthcare as a right, he saw these two opposing positions as mutually exclusive (Gaffney 2018). Similarly, Sade’s recent work posits that government regulation of healthcare and ‘everything else that contributes to good health’ is ‘inconsistent with the notion of a free society’, arguing that regulations and the funding of services via taxation impinge on the freedoms of individuals (Sade 2012).

Much of the debate around the rights and provision of healthcare, *vis-a-vis* the rights of the provider, centre specifically on the role and remuneration of physicians, as clearly encapsulated in Sade’s position (Sade 1971). Allied health professionals are largely absent from the debate. Cruess and Cruess are properly concerned that the medical profession is viewed, almost in parody, as a homogenous monolith, rather than a complex, heterogeneous matrix of interlinked professionals, whose needs, desires, and expectations might not be unified (Cruess and Cruess 2008).

Gaffney notes a further complication in the discussion about the rights of the recipient of care and the provider. Whereas Sade ‘envisions healthcare sold by the individual physician to the individual patient’ (that is, an autonomous, sole-trader provider), the reality is that healthcare is more likely today to be provided by a state or a corporate entity, which employs providers, whose work may be constrained by corporate/government policy.

Similarly, healthcare providers are accountable, not only to their patients, but also to regulatory bodies, government and corporate agencies, including

insurers (Cruess and Cruess 2008). Sade's articulated right to withhold care might also collide with antidiscrimination legislation, if withholding care could be considered illegal because it was judged to be discriminatory. Ultimately, Sade's hypothesized example does not readily align with health systems, nor with the provision of healthcare as it is practised across the developed world. Sade himself acknowledged in a 2012 article, following the introduction of the Affordable Care Act (informally known as 'Obamacare') in the United States, that government had increasingly taken control of healthcare, policy development, and regulation of the health system, although he continues to argue that deregulation will facilitate innovative free market solutions 'guided by the ethical principle of non-interference' (Sade 2012). This libertarian perspective continues to appeal, particularly in the United States, although many such arguments fail to recognize that many corporations now rival nations in terms of their power, influence, and interference in the lives of private citizens (Babic et al. 2017). Indeed, a 2012 article in the *British Medical Journal* introduced the term 'commercial determinants of health' into the lexicon, sitting alongside the social determinants, in recognition of the 'increasingly unhealthy dominance of corporate marketing' (Hastings 2012). Each side of the rights-commodity divide sees fundamental flaws in the opposing position's arguments—a gulf which is unlikely to be reconciled in the foreseeable future, and a debate with which each community and nation must continue to struggle.

Utilitarian perspectives on access to care contend that health services should maximize the health gains obtained by all individuals. This idea is summed up by the slogan 'the greatest good for the greatest number', sometimes regarded as 'the guiding principle for many of the decisions and actions of public health professionals' (Last 2007). The objective of maximizing the health gains to be achieved from available resources is closely related to the economic principle of efficiency, which is the focus of Chapter 6.6 of the current volume. Resources for healthcare will be used most efficiently when health gain is maximized. Equity and efficiency are often viewed as conflicting objectives. For example, delivering equitable access to specialist services in sparsely populated rural areas might compromise efficiency.

The utilitarian approach raises problems because it requires only that the sum of health gains in a population should be maximized. The individual is

not of ultimate concern to the utilitarian. This could result in inefficient allocation of healthcare to individuals with greater needs; the lesser needs of many might be met instead.

By contrast, approaches based on concepts of human rights and social justice view each individual as having a right to healthcare—those needing more will have greater access to care. Proportionality of access was a key concern of the late health economist Gavin Mooney for whom ‘equal access to equal care for equal need’ served as his definition of equity, a definition with which we agree. It was not a guarantee of equal outcomes, biologically impossible to promise, but of equal access.

Responsibility and role of governments

Under the terms of the ICECSR treaty, participating governments bear some responsibility for providing a measure of healthcare to their citizens. However, the treaty does not prescribe how this should be organized, or to what extent governments should fund health systems. The United Nations’ resolution on 12 December 2012 on Global Health and Foreign Policy encourages member states to promote universal health coverage in foreign policy development. The resolution highlights, in particular, the impact of the high cost of care as a barrier to access (UN 2012). Ultimately, each sovereign government must determine how, and to what extent, it is willing or capable of organizing and funding healthcare. The result, globally, is a mix of private, public, and co-payment systems, some tightly controlled by governments and others with minimal regulation or government direction.

The United Nations Sustainable Development Summit, held in New York in 2015, ushered in a series of Sustainable Development Goals (SDG) (UN 2015), (the Millennium Development Goals (MDGs) (UN n.d.) having run their course), which addressed a raft of global challenges to be met by 2030. Target 3. aims to:

> Achieve universal health coverage, including financial risk protection, access to quality essential health-care services and access to safe, effective, quality and affordable essential medicines and vaccines for all. (United Nations (UN), Sustainable Development Goals)

The SDGs call for greater national investment in health and in improvement and maintenance of the health workforce. Success will depend on the extent

to which countries ratify the goals, invest in them, and implement strategies to achieve them.

John McDermott, an expert on public health, agriculture, nutrition and health in Africa, wrote in 2018 ‘universal healthcare is both desirable and possible, even in low income countries’ (McDermott 2018). Stigler et al. propose that universal healthcare is not possible without adequate primary healthcare, which they see as ‘the backbone of an effective health-care system’ (Stigler et al. 2016).

The Economist Intelligence Unit (EIU) report, *Global Access to Healthcare: Building Sustainable Health Systems* (2017) mentions primary healthcare as the ideal basis for a country’s health system—a point where governments can control funding (The Economist Intelligence Unit 2017). Starfield et al. note that health systems which emphasize primary healthcare are more efficient, widen access, reduce inequality, and lower the overall costs of care, while producing better population health and reduced rates of mortality—findings applicable in both national and cross-national analyses (Starfield et al. 2005).

Atun et al. charted the path to universal healthcare in Latin America from the 1980s, through to the early twenty-first century (Atun et al. 2015). Health reforms in Latin America were heavily influenced by the Alma-Ata declaration and therefore placed a strong emphasis on the role of primary healthcare (WHO 1978; Atun et al. 2015). The design and implementation of these universal healthcare systems (UHCs) and the means by which they were funded varied significantly.

With a significant surplus of physicians, the Cuban National Health Service, unlike the healthcare services in Venezuela (see next) has been particularly successful. Following the 1959 revolution, the right to healthcare was enshrined in Cuban law, and universal health services, financed via taxation, began to be developed in the 1970s. Although private healthcare is illegal in Cuba, private spending makes up approximately 10% of all healthcare expenditure. Comprehensive primary healthcare is the lynchpin of the system, with 80% of health problems being managed through healthcare networks centred on polyclinics (Atun et al. 2015).

Extended value of primary health services

Broad definitions of primary healthcare include ‘all the activities whose primary purpose is to improve or maintain health’ (Murray and Frenk 2000), including sanitation, road safety initiatives, or the education of girls. Such multisector interventions, while generally considered to contribute to a community’s health, do not contribute to the care of individuals.

Primary healthcare yields benefits beyond individual recipients. The treatment of pulmonary tuberculosis, for example, reduces the spread of the disease. Such positive ‘externalities’ (outcomes resulting from an intervention in one area but which affect other areas), might be more beneficial for communities than for individuals. Countries might facilitate access to these benefits as ‘merit goods’, underproduced if individuals valued only their own personal benefits.

Extending this argument, it might be desirable to organize care so that it benefits all. For example, the eradication of infectious diseases, or the control of antimicrobial drug resistance, offer benefits extending beyond national boundaries (Smith et al. 2003).

Importance of policy

Section 2 of the current volume examines themes surrounding the determinants of health and disease. Chapter 2.1 examines, in depth, the social determinants of health and Chapter 2.2 explores the relationship between politics and public health. Health inequalities, in both the developed and the developing world, were scrutinized in Chapters 2.4 and 2.5. Health policy has a role to play in each area. Chapters 3.5 and 3.6 examine health policy in greater detail. In this section, we examine the role of health policy as it relates to access to care.

Policies should aim at overcoming barriers to access, many of which intersect with the broader social determinants of health. Poverty, social inequality, location—especially rurality and environment—all affect access.

Low- and middle-income countries wishing to achieve SDG 3.8—the provision of universal healthcare (UHC)—will need policies to lead them towards that goal. Reich et al. examined 11 countries’ pathways towards UHC. These offer lessons for future transitions (Reich et al. 2016). The policy challenges are substantial and wide-ranging. Reich et al. underscore the need for policymakers’ ‘vision and commitment’ to ensure the

successful and sustainable introduction of UHC (Reich et al. 2016). Policies need to address medical and allied health worker training, accreditation, and regulation; service provision; taxation; building the public's trust; and commitment from the public. Starfield et al., also in a comparison of 11 nations, found that 'adequate delivery of primary healthcare services was associated with supportive governmental policies' (Starfield et al. 2005).

To give an indication of the vital importance of policy, we briefly examine the case of Venezuela. During the 1990s, Venezuela began to reform its health system. In 1999, the Venezuelan Constitution recognized healthcare as a fundamental human right (Atun et al. 2015). Funding policies drew on a number of sources, pooled to fund healthcare for the poor, the unemployed, and the rural population. The system was a mix of public and private funding, but with out-of-pocket expenses accounting for more than 50% of health expenditure (Atun et al. 2015). From 2003, a primary healthcare model, *Barrio Adentro*, was introduced, which, for a time, expanded access and resulted in better health outcomes for Venezuela's poorest citizens (Atun et al. 2015). Life expectancy rose and infant mortality dropped dramatically.

By 2013, however, the system was faltering, and by 2016 it was, and still remains, in crisis (Editorial 2018). Economic collapse followed the decline in world oil prices from 2008. For this and other reasons, government spending on public health dropped from 9.1% in 2010 to 5.8% by 2014 (Editorial 2018). The result has been a devastating increase in out-of-pocket payments—a barrier to access for poorer citizens. Maternal and infant mortality have increased. Access to medicines, even for the wealthiest citizens, has diminished due to significant shortages of medications (Fraser and Willer 2016; Editorial 2018). Rather than acknowledge the crisis, the government has ceased gathering data; nor has it, since 2016, reported on the state of the system. Offers of international aid have been declined. The wilful refusal to acknowledge or address the crisis exemplifies a spectacular policy failure. Costing lives it serves as a reminder of the importance and impact which policy implementation can have on access to even the most basic healthcare services.

Financing primary healthcare

Where governments assume a funding role for primary healthcare, policy becomes extremely important. Sustainability is a recurrent challenge. Reich et al. observed that sustaining coverage was a financing and policy issue for each of the 11 nations included in their study (Reich et al. 2016). Decisions undertaken during the development of Ghana's National Health Insurance System resulted in a fee-for-service model, which has proven unsustainable. Ten years after the adoption of the system, the government had to reassess a financially unsustainable system, which did not cover 64% of the population (Reich et al. 2016). Spain implemented a tax-based funding system during the 1980s and 1990s to both expand primary healthcare and ensure the sustainability of the system as a whole (Starfield et al. 2005). Cuba and Brazil similarly fund their universal health system via taxation (Atun et al. 2015).

Cuba has supplemented their taxation funding for healthcare through the provision of healthcare workers to Brazil and Venezuela in exchange for contracted fees paid to the Cuban government (Atun et al. 2015).

The distribution and organization of the healthcare workforce, both state-certified and non-regulated

The Institute for Health Improvement's Triple Aim (Institute of Healthcare Improvement 2009) supports, across differently-resourced regions and populations, the judicious use of 'regulated' (state-certified) and 'non-regulated' health workers. The latter include pharmacy technicians, community health staff, and volunteers.

Throughout the twentieth century, health services have largely been provided by regulated practitioners, such as nurses, midwives, and doctors. But, with need outstripping supply, this workforce is now inadequate, overtrained, and expensive to educate and remunerate. Consequently, workforce development strategies have been developed by the World Health Organization (WHO) to include unlicensed healthcare workers, trained to perform set tasks under the direction and supervision of regulated practitioners. For example, regulated Nigerian health workers make use of churches, mosques, and the premises of their civic organizations as their clinics. Traditional birth attendants assist at childbirth. Community support

is strengthened by recruiting community leaders and prominent citizens as their advocates (Gyuse et al. 2018).

In New Zealand, regulated practitioners, including nurses, midwives, and doctors, may be scarce in rural and remote areas, so the Ministry of Health's strategies make extensive use of non-medical personnel. For example, 'Quitline' advisors available by telephone, text and online, provide smoking cessation advice; and over 50,000 community-based *Kaiāwhina*, or non-regulated care workers and assistants (mainly women), support people with disabilities or chronic illnesses (Health Workforce New Zealand 2018).

Similarly, sudden unexpected death in infancy (SUDI) has been a leading cause of preventable death, the number of SUDI deaths reduced from 250 per year (over 4.4 per 1,000 live births) in the 1980s, to 44 deaths in 2015 (0.92 per 1,000 live births). Although SUDI rates have reduced significantly, they did not fall equitably across the population. The SUDI risk for Maori and Pasifika babies has remained consistently higher than for non-Maori, non-Pasifika babies. Identifying and promoting more effective, culturally appropriate ways of engaging, and staying engaged, with women most at risk of SUDI early in their pregnancies is crucial. A focus on this has resulted in the integration of Kaiiiwhina as community educators into Ministry of Health-directed policy and practice (Health Quality and Safety Commission New Zealand 2017). Likewise, initiatives, including the construction of *wahakura* (woven baskets) for infants to sleep in beside their mothers or other carers, have strengthened community networks for improving health (Abel and Tipene-Leach 2013). Ideally, non-regulated workers belong to the communities of the people they serve, thereby avoiding cultural gaps.

With adequate remuneration, training, and supervision, sufficient resourcing, defined agreed-upon tasks and the support of the community and colleagues, non-regulated workers can successfully manage outbreaks of illnesses such as malaria, and provide preventive care, including vaccination, perinatal care and health promotion (Haines et al. 2007). In a poor rural community in Pakistan, with little access to mental healthcare, integration of a cognitive behaviour therapy-based intervention into the routine work of community health workers more than halved the rate of depression in prenatally depressed women compared with those receiving enhanced 'usual' care (Rahman et al. 2008). These types of initiatives

demonstrate the potential to integrate similar roles for community health workers into other health systems, particularly in resource-poor settings.

In 2010, WHO called for the more effective use of non-regulated healthcare workers. It stressed an urgent, global need to strengthen primary healthcare, to integrate interprofessional education and collaborative practice into service, education, and health policy. That need has not abated.

In the light of budgetary constraints, primary healthcare remains one of the best investments governments can make (The Economist Intelligence Unit 2017; Mossman et al. 2017). For example, initiatives to tackle the dearth of medical practitioners in rural areas can focus on non-medical providers (Sanne et al. 2010; Fairall et al. 2012), such as nurse practitioners, to provide certain types and levels of care. New Zealand, with a population of nearly five million, including 15,000 doctors, employs more than 300 nurse practitioners throughout the country. Nurses qualify as practitioners upon gaining a clinical master's degree in addition to the three-year bachelor's degree. Those in primary healthcare can diagnose, treat, and prescribe and, like general medical practitioners, might be the lead healthcare provider. Each costs a fraction of the cost of educating and maintaining a medical practitioner. These nurses are often residents of the rural communities and small towns to which, following education and registration, they return.

Technology can support access to primary healthcare. For example, the *Mohalla* clinics in Delhi operate low-cost kits for common medical tests (Lahariya 2017), reducing the costs of screening and treatment for diabetes, dengue fever, and hepatitis. In Rwanda and many other countries, telehealth is being trialled to carry medical advice to rural and remote patients (The Economist Intelligence Unit 2017). Like the Royal Flying Doctor Service of Australia, one of the largest and most comprehensive aeromedical organizations, telehealth is an important mechanism for enhancing access, team-based care, and quality of care for patients in rural and remote Australia (Bradford et al. 2016).

Services such as the North Star Alliance, based in sub-Saharan Africa, support low-level continuing care, delivered via programmes which align with patients' experiences in a culturally responsive way, providing local support, which requires less travel, resulting in shorter waiting times. The North Star Alliance also uses clever branding and marketing to reach patients and the communities they interact with. Their not-for-profit

network includes more than 30 roadside health clinics at disease hotspots on major transport routes used by mobile workers, travellers, and displaced persons who frequently cross borders, thereby increasing the risk of disease spreading across borders (North Star Alliance 2018). Such services offer the convenience of enabling the patient's daily life to continue.

The Le-Nest initiative in Shanghai offers an inexpensive service for patients whose diabetes and hypertension can be managed in primary healthcare (International Partnership for Innovative Healthcare Delivery 2014). Such services are readily accessible for either an acute, minor problem, or a flare-up of a long-standing illness. Similarly, the Practical Approach to Care Kit (PACK) programme, offered through *The British Medical Journal*, offers non-physician clinicians in low- and middle-income countries a suite of checklists and algorithms for screening, diagnosis, and treatment for a range of commonly presented symptoms, acute and chronic conditions that can be managed within the community (Fairall et al. 2018).

The role of data in planning, monitoring, and evaluating services

To try to assure the quality of primary healthcare, health key performance indicator (KPI) data are used internationally. They allow comparison of performance among different locations as well as system-wide improvements and reforms. They can establish goals for access to care and specify the extent, type, and cost of care (Hibbert et al. 2013). They can be linked to clinical and financial measures of achievement and outcome. The range of KPIs is widening as a result of the introduction of new technologies, and of expanding the expectations of those who use and pay for services.

The place of KPIs in assessing the managerial machinery, clinical processes, and financial performance of healthcare systems is deeply entrenched. They have tended to relate to everything except the details of what the health system achieves in improving health and quality of life of patients. These provoke profound clinical scepticism, especially when accompanied with demands for copious data collection by busy clinicians. There is a tendency to measure what can easily be measured. Important

qualitative aspects are pushed aside by narrow quantitative measures. This often reduces the focus to concerns with process and activity rather than with access or outcome.

Despite these limitations, the need for KPIs is clear. Comprehensive primary healthcare using integrated, team-based services for those with multiple comorbidities is short on evidence of its effectiveness. Evaluation using performance indicators, reflecting both equity, outcome, and accessibility of care, will be crucial to advancing the effectiveness of primary healthcare (McDonald 2016).

Several serious questions should be asked of policymakers who increasingly make use of the collected data for measuring performance:

What is the purpose of the service whose performance is being assessed?
Do the KPIs relate clearly and unambiguously to that purpose?
How are performance measures being used in practice?
What are the consequences of poor performance? Education? Penalties? Dismissals?
What changes in funding, system and outcomes have occurred as a result of spending time and treasure in obtaining and analysing performance data?
What could improve the use of performance measures and the data they generate?

Although outcome data are difficult to procure and contain no magical answers, appropriate publication of such data drives improvements in the quality of care (Fung et al. 2008).

The New Zealand Health Quality and Safety Commission recently launched a dashboard of healthcare system quality indicators (Health Quality and Safety Commission New Zealand 2018). This provides data on 60 measures for each local district. Quality measures include timely access, safety, effectiveness, patient-centredness (including satisfaction) and equity. These measures and scales, which compare each district with the national average, support continuous improvement.

Conclusion

Regardless of a country's wealth, political commitment and public investment make the difference between sustainable and unsustainable access to healthcare. While less affluent countries are more likely to struggle with the sustainability of such developments, several are improving impressively.

A commitment by leadership—within countries, governments, and health organizations—to improving healthcare access is crucial if progress is to occur.

While overcoming geographical and financial barriers is important, so is a focus on workforce initiatives. Many of these seek to improve access to primary healthcare through intermediaries such as community health workers and health practitioners, who have the time to build trusted relationships with communities and patients.

Healthcare systems can support access by articulating a narrative which explains and inspires, designating expectations through strategy, policy, and funding formulas, to ensure that communities are engaged in the development, implementation, and monitoring of improvements to healthcare access. When informed by the analysis and use of local data to plan and monitor services, models of care can more closely fit the demand and the need for good access to care.

Access to healthcare is not only about entry to the healthcare system, but also about the journey through it. Committed and responsive staff is vital. For all these reasons, organizing optimal access to primary, secondary and tertiary services, in combination, warrant further research and development to achieve optimal management of communicable and NCDs, and to promote health through frontline preventive services.

ACKNOWLEDGEMENT

This chapter draws in part on the contribution to the previous edition of this textbook by Martin Guilford. We extend our thanks to him for his generosity. We are also grateful to Dr Peter Arnold OAM, of Sydney, for extensive editorial support in preparing this chapter.

Leadership in public health

Kevin A. Fenton

What is leadership?

At its core, leadership is the art of motivating a group of people to act towards achieving a common goal. In the health and care setting, this can mean directing workers and colleagues with a strategy to meet either the organization's or community's needs. The leader is the inspiration and director of the action, and possesses the combination of personality and leadership skills that makes others want to follow their direction. US academic environments define leadership as 'a process of social influence in which a person can enlist the aid and support of others in the accomplishment of a common task'.[1][2] Studies of leadership have produced theories involving traits,[3] situational interaction, function, charisma, behaviour,[4] power, vision and values, [5] among others.[2]

If public health describes the organized efforts of society to improve health and tackle inequalities (UK Faculty of Public Health 2016), then leadership in public health represents the characteristics, passion, strategies, and abilities required to effect those changes. For too long public health practice and scholarship have focused on the skills required to characterize population health need, identify evidence-based approaches for addressing them, and more recently, a focus on implementation science and research to understand how evidence-based interventions are developed, implemented, and evaluated to improve population health outcomes. However, comparatively less attention had been paid in understanding the unique role, needs capacity, and importance of public health leadership and how this interfaces with policy, politics, or a range of competing interests.

In a world increasingly characterized by growing complexity and interdependencies, worsening health, social, and economic inequality,

competing social, environmental, and commercial interests, declining trust in government, and worsening social isolation and loneliness, now more than ever is the time and opportunity for public health leadership and leaders to shine. We have a unique opportunity to lead from the front: encouraging the move away from individual-focused interventions to tackling the wider (e.g. social, structural, economic) determinants of health and well-being; identifying evidence informed solutions to wicked problems (from youth violence, non-communicable disease control, to climate change); using data (both big and routine) to inform better targeting and prioritization of strategies and resources; and working with, empowering and engaging communities in new, meaningful, and more efficient ways. To achieve this public health leadership in the twenty-first century must be bold, confident, agile, innovative, inspirational, and capable of working within and across systems.

This truly is an exciting time to be a leader in public health and the ability to truly make a difference in the lives of millions at home and abroad a privilege for practitioners at home and abroad.

Leadership is not the same as management

Today, rather than viewing leadership as a set of innate qualities, we can think of the primary traits that leaders have in common which include having a positive outlook and forward thinking—being sure of themselves and their ability to influence others and impact the future.

Much literature and research conflate leadership and management, but the two are not identical: ‘Management’ derives from the Latin word ‘manus’ (meaning hand) and the subsequent Italian word ‘maneggiare’ (to control, often horses). ‘Leadership’, however, is from the Old German word ‘Lidan’ and the Old English derivation ‘lithan’ (to travel, to show the way, to guide) (Grint 2002, p. 248). Although similar, leadership and management are different: leadership goes beyond and above management. A manager can be organized and efficient in getting tasks done without a leader—someone who inspires others to achieve their best. Whereas managers manage processes; leaders lead people and organizations. Leadership is the most basic and scarcest resources in any business enterprise (Peter Drucker), of which the health and care sector is no exception.

Being an effective manager is important in public health practice. Management is no means an easy task and requires individuals to have a range of skills that may take many years to develop. Good public health managers are able to operate effectively and efficiently. They are able to take their organizations through change to accomplish goals and achieve objectives. Good managers tend to focus on the here and now as they are often expected to deliver and achieve outcomes in the short term. Good organizations rely on good managers; however, great management does not necessarily make a good organization.

Competent management is critical for successful delivery of public health programmes. It drives the ability to take care of the controlling and critical tasks required for effective programme implementation, monitoring, and evaluation. Good managers are increasingly involved in evidence informed practice, implementation science and programme research—all needed to improve management in order to strengthen the functioning of health systems (see, for example, Egger et al. 2005). This distinction between the controlling tasks associated with implementation and the visionary activities associated with setting a direction is a useful way of distinguishing management and leadership. In practice, the two are often linked either in a single individual or in a particular job description. Indeed, the vast majority senior and effective public health leaders rose through the leadership ranks based on a combination of technical, interpersonal, managerial, and leadership competences, acquired at different phases and stages of their career. As a result, separating the characteristics of good leadership from those of good management is not straightforward. However, the distinction between the leadership role and the managerial role is widely perceived as the difference between vision and implementation.

Leadership and good leadership are about having vision. The ability to look beyond the here and now to see the vast potential for one’s organization. Leadership deals with interpersonal influence, and management deals with acquiring and allocating resources to achieve work, unit or organisational goals (Campbell 2013, p. 412). Leadership is, therefore, broader than the leading of employees within organizations. Leadership takes place in all social and political contexts. Great leaders are also effective in getting things done but they accomplish their goals in different ways from managers. Leaders challenge their employees to achieve goals by creating a compelling vision for the future and then unlocking their

employees' potential to do so. Without the vision that leaders provide and without the contribution of their followers' hard work, energy, and innovation, we would never have achieve many of the excellent milestones in public health: from the global eradication of small pox and eradication of many vaccine preventable diseases, to the progress made in understanding and responding to the AIDS pandemic, and addressing more recent health threats including Ebola, and non-communicable diseases (NCDs). 'In public health, leaders are needed not only in hospitals and department divisions, but also in local, regional, and national government, in other related sectors like education and in large- and small-scale settings.

These distinctions between leaders and managers apply perfectly well in the public health sector. For example, the public health director of a health district might choose to have an operations manager who manages the finances, commissioning, and daily programme implementation, thereby allowing themselves the freedom to develop strategies and engage diverse actors and system partners in a shared vision of the district's health goals. A public health agency, to give another example, needs managers who, with limited finances, can organize and implement international, national, or local programmes; develop, implement, and evaluate public health policies; and manage programme staff and resources effectively. In both examples, health districts and public health organizations will also need leaders who can motivate staff to provide high-quality work in the context of budget restrictions and sociopolitical and economic uncertainty. Sometimes these skills and job responsibilities may exist in the same person, but the nature of management tasks differ from leadership tasks.

In this chapter, we are particularly interested in leadership rather than management. Public health requires people who can move the agenda in a world dominated by the politics of vested interest groups and where government policies may have intended and unintended consequences impacting population health and well-being. It requires individuals who can take scientific evidence and use it to help change the direction of policy. It requires leaders who can consistently and competently operate from place of authenticity, with clear vision, values and purpose, and an ability to lead across organizations and systems. These challenges call for 'big picture' skills, in addition to our core public health competences, and the ability to influence people both inside and outside the public health field.

Evolution of leadership theory

Research on leadership, like that on management, has evolved over time (Van Wart 2003). More than a century ago, thinking about leadership focused on the inherent personality of the individual leader: 'This 'Great Man Theory' approached leadership capacities as innate, fixed, and cross-contextual … the leader as solitary actor' (Turning Point 2001, p. 14).

This 'great leader' theory was deepened, in the first part of the twentieth century, by attempts to identify the key 'traits' or 'attributes' of successful leaders. Leadership attribute research was still focused on the individual, not the context. This research has continued into the present day and has generated many lists of leader traits (Zaccaro et al. 2013), including some specific to the health sector, as we show in the next section. The 'special individual' has certainly been invoked in the health sector. For example, Halfdan Mahler, a former head of the World Health Organization (WHO), and James Grant, a former head of UNICEF, were widely thought to have innate leadership qualities that largely explained the success of their agendas. When engaging colleagues who have risen to senior executive public health leadership positions within UK and internationally (as part of the background research for this chapter), a recurring characteristic is that these leaders bring a clarity of vision and strong personal values to their work, aligned with their organization's missions, are willing to take risks and to do things that defy convention, using innovation, partnerships, or disruption to achieve different outcomes. Relatively few of these leaders are autocratic or 'heroic leaders', using the power of their position to make decisions unilaterally. In contrast, they are often expert facilitators, leading from a position of authority, and utilizing a participatory decision-making style, using skilful questions to draw ideas out of others to develop shared solutions.

Research and thinking on the question of leadership moved on in the middle of the twentieth century to a 'contingency' approach (Van Wart 2003), taking into account the attributes not only of the leader, but also of the followers and the context in which he or she leads, for a more nuanced understanding of leadership success. While acknowledging that 'the essence of leadership is influence', this approach accepts that 'no single leader trait … or style explains leadership in all circumstances' and focuses instead on 'the dynamics of leadership—the coming together of leader and follower

behaviour in a social and/or organisational context' (Rumsey 2013a, pp. 1, 2, and 6; see also Rumsey 2013b).

What do leaders do?

Today the skills required to be a good leader are no longer secret, nor are they considered to be innate traits bestowed upon special individuals. Although some people seem to be born to be leaders, anyone can discover what leaders do and how to apply these skills in their everyday practice. This underscores the importance for those interested in developing their leadership skills to invest time shadowing and mentoring by experienced leaders. Types of leadership are outlined in Box 3.1.1.

Box 3.1.1 Methods of leadership

In many, or perhaps most, organizations, more than one of these conceptions may define leadership. Each implies particular ways of leading, and leaders may use a number of different methods.

Pure exercise of power. 'My way or the highway.' If you don't do what the leader demands, no matter how unreasonable, you're gone. The leader's decisions are not open to question or discussion, and no one else gets to make decisions.

Political scheming. The leader plays people off against one another, creates factions within the organization, cultivates 'allies' and isolates 'enemies', and builds up (through favours or overlooking poor performance) personal debt which can be cashed in when needed, in order to manipulate people and events as he wishes.

Using relationships. The leader develops strong positive relationships with all or most of the people in the organization and uses these relationships to steer people in particular directions. People do what they're asked because of their relationships with the leader, rather than for reasons connected to the tasks themselves.

Setting an example. The leader may or may not demand or request particular behaviour or actions, but she will demonstrate them, and expect or imply that others will follow.

Persuasion. The leader convinces people through argument, reasoning, selling techniques, or other persuasive methods that what the leader wants is, in fact, the best course, or in line with what they want to do.

Sharing power. Some leaders choose to exercise at least some leadership through the other stakeholders in the organization. In this situation they may give up some personal power in return for what they see as more ownership of decisions, goals, and the organization itself by those involved in the decision-making process.

Charisma. Some leaders are charismatic enough to simply pull others along by the power of their personalities alone. They may, in fact, advocate and accomplish wonderful things, but they do it through people's loyalty to and awe of them.

Involving followers in the goal. The leader gets others to buy into his/her vision for the organization, and to make it their own. He/she may accomplish this through charisma, through the

force of her own belief in the power and rightness of the vision, or through the nature of the vision itself.

Inspire action

Most workers want to feel pride in their organization and when given the chance would give over and beyond for a cause that they believe in. This is especially so for individuals working in public health who are often drawn to the field in order to serve society, a commitment to social justice, and the desire to make a difference in their community, country, or globally. This means that there is much innate passion, creativity, and energy to draw upon in organizations. Effective public health leaders are able to use this knowledge to inspire employees to take action and achieve great things. This may be achieved by removing barriers and roadblocks to creativity, giving positive feedback and a sense of pride to employees, and creating a compelling vision for employees to strive for. Leaders help employees to tap into energy and initiative that employees did not know they had.

Communicate

Leaders make a commitment to communicate with their employees and to keep them informed about the organization. Great leaders earn the commitment of their workers by building communication links throughout the organization by providing regular feedback on performance, sharing positive news and results, publicly acknowledging the successes of individual workers and teams, keeping internal and external stakeholders well briefed of the contributions and priorities of the team, and providing opportunities for two-way communication and feedback. Duncan Selbie, Public Health England (PHE) 's Chief Executive circulates a Friday Message (e-newsletter) which informs tens of thousands of staff and agency partners nationally and globally about PHE's activities and accomplishments of the week. The agency's Health Matters resource is an effective way of engaging and communicating with broader system partners nationally on public health policies and initiatives.

Support and facilitate

Great leaders create environments in which employees are safe to speak up, tell the truth, innovate, and take risks. This is especially crucial in public health programmes where the failure of teams and the workforce to do so can result in errors with resultant harm to individual and communities. The ability to innovate and take risks is especially important for public health teams that are often faced with delivering complex population health programmes under challenging political circumstances and with financial and resource constraints and pressures. Good leaders support their employees and facilitate their ability to reach their goals. Great leaders are able to support employees, especially when times get rough. Great leaders are always there in the background—ready to assist and support workers were necessary.

Leadership traits

We have all worked with individuals who we or other consider to be great or poor leaders and seldom find it difficult to describe the traits or behaviours which contribute to this perception. The way that we manage ourselves is a central part of being an effective leader. Personal qualities like self-awareness, self-confidence, self-control, self-knowledge, personal reflection, resilience, and determination are the foundation of how we behave. Being aware of your strengths and limitations in these areas will have a direct effect on how you behave and interact with others, and they with you.

Optimism

Great leaders are more likely to envision a brighter more positive future, with great promise and optimism. This is often despite finding adversity and hard work on the way to achieving their goals. This ability to fixate on the future combined with optimism creates an aura that radiates from all leaders and touches those with whom they are in contact. Ultimately, people want to feel good about themselves and their futures and they want to work with organizations that are making a positive difference for their staff as well as the people they serve. In day-to-day practice in a busy public health department, this is not about being naïve about or ignoring the challenges

and problems faced by the team, but rather placing these within the context of other accomplishments, opportunities, and potential early wins. This reframing can be especially motivating for teams who often are unable to see the bigger or more strategic opportunities that the leader will have access to.

Confidence and decisiveness

Confident leaders make confident followers. An organization's employees mirror the behaviours of their leaders. When leaders are tentative and unsure of themselves so are the workers. When leaders display self-confidence workers follow. The nature of public health practice means that we are constantly making decisions: what evidence to use; which priorities to address; which programmes to commission; how best to evaluated them; and how to drive and improve health impact. Being decisive avoids waiting for the course of events to make decisions for the organization or individual. Often making a decision is better than making no decision at all. Great leaders are decisive. They take the time necessary to gather information on a problem, the people and resources needed to make an informed decision within a reasonable time frame. If the data are not available then the leader carefully weights the available data and information against the relative need of the decision and acts accordingly.

Integrity

Integrity is often highlighted as a most desirable trait that employees want from their leaders, and in public health, the finding is the same. Ethical behaviour, values, and a sense of fair play are key characteristics of effective leaders. Honest people want to follow honest leaders. When an organization's leaders conduct themselves with integrity, the organization can make a real difference in the lives of its employees, customers, and others who come into contact with it. Maintaining high standards of ethical and scientific integrity helps to maintain public trust in both the work of government, national and local, as well as research enterprises.

The UK General Medical Council, in articulating the duties of all doctors registered to practice, are clear that patients must be able to trust doctors with their lives and health. To justify this trust doctors must show respect for human life and make sure our practice meets the standards expected.

Maintaining trust is a one of four domains of ethical practice for UK physicians. This has implications for both public health practice and research, and the UK's Faculty of Public Health Good Public Health Practice Framework (2016) provides guidance on good professional practice in public health. It applies to all members of the core public health workforce, including public health practitioners and specialists and those training to become practitioners and specialists. It requires all involved, and especially leaders to behave in appropriate ways with a commitment to intellectual honesty and personal responsibility for one's actions as a researcher and practitioner. See Box 3.1.2.

Box 3.1.2 United Kingdoms' Faculty of Public Health. Good Public Health Practice Framework Short Guide (2016)

Maintaining the Public's Trust: Probity and Protecting the public

1. You must ensure at all times that your standards of practice justify the public's trust in your work, and in the work of the wider public health profession. Probity is the cornerstone of good public health practice. The components of probity are:
    a. Integrity: Put your service obligations above your personal interests;
    b. Honesty: Be truthful and open;
    c. Objectivity: Base advice and decisions on rigorous analysis of evidence;
    d. Impartiality: Act solely according to the merits of a case without prejudice.
2. You must disclose professionally facts which may have a bearing on your professional performance.
3. You must be vigilant about issues concerning data confidentiality and data protection.
4. You must respond to concerns and complaints.
5. You must be honest and objective when assessing the performance of those you have supervised, trained, or worked with.
6. You must be honest and trustworthy when writing reports, and when completing or signing references, forms, reports, and other documents.
7. You must co-operate with legitimate requests for information from official organizations monitoring public health.
8. You must respond, when and where you are able, in emergencies.
9. Your advertising of your services must be truthful, honest, legal, and decent.

Emotional intelligence

Emotional intelligence (sometimes referred to as EQ or EI) is the ability to comprehend, control, and develop your own feelings, while also being able to understand and manage others' feelings (Box 3.1.3). (Ref) Emotionally intelligent leadership emphasizes how one's emotions affect others and how you can use that knowledge to create positive outcomes—both personally and with the people you manage. The best leaders are self-aware of not only their emotions, but also their weaknesses and limitations, as well as their strengths. People with high emotional intelligence have a good understanding of their own emotional states, which allows them to better gauge the emotions of others. Emotional intelligence (EI) accounts for 85–90% of the difference between outstanding leaders and their more average peers (Ref). These benefits all have something in common: the enhanced EI leaders have developed produces positive results in their employees, helping to build better teams, and help prevent employee turnover.

EI includes four domains: self-awareness, self-management, social awareness, and relationship management. The first two domains determine how well we understand and manage ourselves and our emotions. The latter two dictate how well we recognize and manage the emotions of others, build relationships, and work in complex social systems. The four qualities contain 18 leadership competences all of which support the development of resonance. Together when developed these competencies have benefits to both individuals (self-regulation, less stress, more empathy, collaborative communication) as well as the organization (team management, corporate culture, better outcomes).

Box 3.1.3 Emotional intelligence domains and competences

Personal competence: These capabilities determine how we manage ourselves

Self-awareness

- Emotional self-awareness: Reading one's own emotions and recognizing their input; using gut sense to guide decisions
- Accurate self-assessment: Knowing one's own strengths and limits
- Self-confidence: Having a sound sense of one's self worth and capabilities

Self-management

- Emotional self-control: Keeping disruptive emptions and impulses under control
- Transparency: Displaying honest, integrity, and trustworthiness
- Adaptability: Demonstrating flexibility in adapting to changing situations or overcoming obstacles
- Achievement: Having the drive to improve performance to meet inner standards of excellence
- Initiative: Being ready to act and to seize opportunities
- Optimism: Seeing the 'upside' in events

Social competence: These capabilities determine how we manage relationships.

Social awareness

- Empathy: Sensing other's emotions, understanding their perspectives, and taking active interest in their concerns
- Organizational awareness: Reading the currents, decision networks, and politics at the organizational level
- Service: Recognizing and meeting follower, client, or customer needs

Relationship management

- Inspirational leadership: Guiding and motivating with a compelling vision
- Influence: Using a rage of tactics for persuasion
- Developing others: Bolstering other's abilities through feedback and guidance
- Conflict management: Resolving disagreements
- Building bonds: Cultivating and maintaining a web of relationships
- Teamwork and collaboration: Fostering cooperation and team building

Leadership styles

Today's context for health leadership is complex, rapidly evolving, and calls for new approaches to the development of leaders for today and the future. According to John Gardner, in *On Leadership*: 'Leadership is the process of persuasion or example by which an individual (or leadership team) induces a group to pursue objectives held by the leader or shared by the leader and his or her followers.' If we accept that definition, then leadership style is the way in which that process is carried out.

Leaders' styles encompass how they relate to others within and outside the organization, how they view themselves and their position, and—to a very large extent—whether or not they are successful as leaders. If a task needs to be accomplished, how does a particular leader set out to get it done? If an emergency arises, how does a leader handle it? If the organization

needs the support of the community, how does a leader go about mobilizing it? All of these depend on leadership style (Box 3.1.4).

Box 3.1.4 Summary of leadership styles

Visionary. This style is most appropriate when an organization needs a new direction. Its goal is to move people towards a new set of shared dreams. 'Visionary leaders articulate where a group is going, but not how it will get there—setting people free to innovate, experiment, take calculated risks,' write Mr Goleman and his co-authors.

Coaching. This one-on-one style focuses on developing individuals, showing them how to improve their performance, and helping to connect their goals to the goals of the organization. Coaching works best, Mr Goleman writes, 'with employees who show initiative and want more professional development'. But it can backfire if it's perceived as 'micromanaging' an employee, and undermines his or her self-confidence.

Affiliative. This style emphasizes the importance of teamwork, and creates harmony in a group by connecting people to each other. Mr Goleman argues this approach is particularly valuable 'when trying to heighten team harmony, increase morale, improve communication, or repair broken trust in an organization'. But he warns against using it alone, since its emphasis on group praise can allow poor performance to go uncorrected. 'Employees may perceive,' he writes, 'that mediocrity is tolerated.'

Democratic. This style draws on people's knowledge and skills, and creates a group commitment to the resulting goals. It works best when the direction the organization should take is unclear, and the leader needs to tap the collective wisdom of the group. Mr Goleman warns that this consensus-building approach can be disastrous in times of crisis, when urgent events demand quick decisions.

Pacesetting. In this style, the leader sets high standards for performance. He or she is 'obsessive about doing things better and faster, and asks the same of everyone'. But Mr Goleman warns this style should be used sparingly, because it can undercut morale and make people feel as if they are failing. 'Our data shows that, more often than not, pacesetting poisons the climate,' he writes.

Commanding. This is classic model of 'military' style leadership—probably the most often used, but the least often effective. Because it rarely involves praise and frequently employs criticism, it undercuts morale and job satisfaction. Mr Goleman argues it is only effective in a crisis, when an urgent turnaround is needed. Even the modern military has come to recognize its limited usefulness.

All leadership styles can become part of the leader's repertoire. Leadership styles should be adapted to the demands of the situation, the requirements of the people involved and the challenges facing the organization. In the book *Primal Leadership*, Daniel Goleman, who popularized the notion of 'Emotional Intelligence', describes six different styles of leadership. The most effective leaders can move among these styles, adopting the one that meets the needs of the moment. They can all become part of the leader's repertoire.

The style of an organization's leadership is reflected in both the nature of that organization and its relationships with the community. In many ways,

the style of its leader defines an organization. If the organization is to be faithful to its philosophy and mission, its leader's style must be consistent with them. For that reason, being conscious of both your own style as a leader and those of others you hire as leaders can be crucial in keeping your organization on the right track.

Collaborative leadership (Leadership FD P 54)

Collaborative leadership has always been a hallmark of leading in public health organizations. In part driven because of the need for leaders to move beyond working with a few individuals on the management team at the top of their organizations and understanding that to get the most of your employees and to maximize public health outcomes and outputs, we need to continue to get the most out of every employee. A collaborative leader tries to involve everyone in the organization in leadership. She is truly first among equals, in that she may initiate discussion, pinpoint problems or issues that need to be addressed, and keep track of the organization as a whole, rather than of one particular job. But decisions are made through a collaborative process of discussion, and some form of either majority or consensus agreement. Towards that end, a collaborative leader tries to foster trust and teamwork among the staff as a whole.

Collaborative leadership comes as close as possible to ensuring that members of the organization buy into its vision and decisions, since they are directly involved in creating them. See Box 3.1.5. It comes closest to the goal of servant leadership, and it also comes closest to reflecting the concepts of equality and empowerment included in the philosophy and mission of so many grass roots and community-based organizations. It thus removes much of the distrust that often exists between line staff and administrators.

Box 3.1.5 8 Principles of collaborative leadership used in Orpheus Process

- Put power in the hands of people doing the work
- Encourage individual responsibility for product and quality
- Create clarity of roles
- Foster horizontal teamwork
- Share and rotate leadership
- Discover how to listen, discover how to talk
- Seek consensus (and build creative systems that favour consensus)
- Dedicate passionately to your mission

Democratic leadership

Democratic leadership invites the participation of staff members and others, not only in decision-making, but in shaping the organization's vision. It allows everyone to express opinions about how things should be done, and where the organization should go. By bringing in everyone's ideas, it enriches the organization's possibilities. But it still leaves the final decisions about what to do with those ideas in the hands of a single person. A democratic leader understands that there is no organization without its people. Although he sees the organization as a cooperative venture, he knows that he ultimately has to face the consequences of his decisions alone.

Some models of democratic leadership might put the responsibility in the hands of a small group—a management team or executive committee—rather than an individual. What a democratic leadership doesn't necessarily do—although it can—is establish staff ownership of the organization and its goals. Although everyone may be asked for ideas or opinions, not all of those are used or incorporated in the workings of the organization. If there is no real discussion of ideas, with a resulting general agreement, a sense of ownership is unlikely. Thus, democratic leadership may have some of the drawbacks of autocratic leadership—a lack of buy-in—without the advantages of quick and clear decision-making that comes with the elimination of consultation.

Managerial leadership

The leader who sees themself as a manager is concerned primarily with the running of the organization. Where it's going is not at issue, as long as it gets there in good shape. Depending upon the nature and stability of the

organization, his/her main focus may be on funding, on strengthening the organization's systems and infrastructure (policies, positions, equipment, etc.), or on making sure day-to-day operations go well (including making sure that everyone is doing what he's supposed to).

An efficient managerial leader will generally be on top of what's happening in the organization. Depending on the size of the organization and her management level, she'll have control of the budget, know the policies and procedures manual inside out, be aware of who's doing his job efficiently and who's not, and deal with issues quickly and firmly as they come up. What she won't do is steer the organization. On the other hand, good management without a clear vision creates an organization with no sense of purpose. The organization may simply act to support the status quo, doing what it has always done in order to keep things running smoothly.

Transformational leadership

The idea of transformational leadership was first developed by James McGregor Burns in 1978 and later extended by Bernard Bass as well as others. Neither Burns nor Bass studied schools but rather based their work on political leaders, Army officers, or business executives. Transformational leadership looks at leadership differently. It sees a true leader as one who can distil the values and hopes and needs of followers into a vision, and then encourage and empower followers to pursue that vision. The transformational leader conceives of leadership as helping people to create a common vision and then to pursue that vision until it's realized. She elicits that vision from the needs and aspirations of others, gives it form, and sets it up as a goal to strive for. The vision is not hers: it is a shared vision that each person sees as his own.

The conception behind transformational leadership is thus providing and working towards a vision, but also has elements of empowerment, of taking care of people, and even of task orientation. The job of the transformational leader is not simply to provide inspiration and then disappear. It is to be there, day after day, convincing people that the vision is reachable, renewing their commitment, priming their enthusiasm. Transformational leaders work harder than anyone else, and, in the words of a spiritual, 'keep their eyes on the prize'.

The methods that transformational leaders might use to reach their goals can vary. They'll virtually always include involving followers in the goal, as well as charisma, which comes, if not from personal characteristics, from the ability to put a mutual vision into words, and to move a group towards the realization of that vision. Transformational leaders may also use sharing power, setting an example, and/or persuasion to help move a group towards its goal. Leithwood finds that transformational leaders pursue three fundamental goals:

Autocratic leadership

Autocratic leaders insist on doing it all themselves. They have all the power, make all the decisions, and don't often tell anyone else about what they're doing. If you work for an autocratic leader, your job is usually to do what you're told. An autocratic leader often maintains his/her authority by force, intimidation, threats, reward and punishment, or position. Although he/she may or may not have a clear vision, and may or may not be steering the organization in the right direction, he's not concerned with whether anyone else agrees with what he's doing or not.

Autocratic leadership allows quick decision-making, and eliminates arguments over how and why things get done. At the same time, however, it may reduce the likelihood of getting a range of different ideas from different people, and can treat people badly, or as if they don't matter. If, as is often true, the leader is concerned with his own power and status, he'll be looking over his shoulder, and moving to squelch any opposition to him or his ideas and decisions. Innovation or the use of others' ideas is only permissible if it's part of the leader's plan.

Autocratic leaders often leave fear and mistrust in their wake. Others in the organization tend to copy their protection of their position, and their distrust of others' ideas and motives. At its best (and there are decent autocratic leaders), autocratic leadership provides a stable and secure work environment and decisive, effective leadership. All too often, however, it can sacrifice initiative, new ideas, and the individual and group development of staff members for the predictability of a highly structured, hierarchical environment where everyone knows exactly what he's supposed to do and follows orders without question.

Systems leadership

Transforming a complex system—such as the transportation, housing, or food system, all wider determinants of health—is a monumental task requiring coordinated action by people with very different viewpoints. Systems change initiatives often engage hundreds of organizations—governments, companies, civil society organizations, worker associations, research institutions and others—combining their capacities to achieve a shared goal.

Systems leadership is about how you lead across boundaries—departmental, organizational, or sectoral. It's how you lead when you're not in charge, and you need to influence others rather than pull a management lever (Ref). See Boxes 3.1.6 and 3.1.7.

It describes the way the leader needs to work when faced with large, complex, difficult, and seemingly intractable problems; where you need to juggle multiple uncertainties; where no one person or organization can find or organize the solution on their own; where everyone is grappling with how to make resources meet demand which is outstripping them; and where the way forward therefore lies in involving as many people's energies, ideas, talents, and expertise as possible.

It recognizes that leadership isn't vested in people simply because of their title or position; that it is possible, and often necessary, for leadership to be shared and ceded. To achieve success, partners must come together on the basis of a shared ambition, and accept partial or clumsy solutions on the way to getting there. Working with uncertainty, and ambiguity, is a given, and it's expected that people will experiment with different methods and processes as a result.

Box 3.1.6 Key steps in effective system leadership

We distilled five key elements of the systems change process into the 'CLEAR' framework for leading systems change. These five elements are not necessarily sequential—they may overlap or repeat in cycles throughout the course of an initiative.

2. Convene and commit

Key stakeholders engage in moderated dialogue to address a complex issue of mutual concern. They define shared interests and goals, and commit to working together in new ways to create systemic

change. For example, the We Mean Business Coalition engaged nearly 1,000 leading companies to advocate for ambitious, science-based climate policy, and has made over 1,500 action commitments.

3. Look and learn

Through system mapping, stakeholders jointly build a shared understanding of the components, actors, dynamics, and influences that create the system and its current outcomes, generating new insights and ideas.

For example, The Global Alliance for Improved Nutrition targets specific gaps in the nutrition system, working to catalyse and scale market-based solutions, and targeting vulnerable populations who are most in need.

4. Engage and energize

Strong stakeholder engagement is built through continuous communication to build trust, commitment, innovation, and collaboration. Inspiration, incentives, and milestones help drive progress and maintain momentum. For example, the New Vision for Agriculture initiative engaged over 650 organizations and 1,500 individual leaders around the world, catalysing action in 21 countries including over 90 value-chain projects.

5. Act with accountability

Shared goals and principles set the direction of the initiative, while measurement frameworks help track progress. Coordination and governance structures can be developed as initiatives mature. For example, the Every Woman Every Child movement mobilized hundreds of action commitments towards its global strategy, monitoring progress through a unified accountability framework, with oversight from a high-level steering group and coordination by a global secretariat.

6. Review and revise

Stakeholders review progress regularly and adapt their strategy accordingly. Adopting an agile, flexible, innovative, and learning-centred approach allows for evolution and experimentation. For example, the 2030 Water Resources Group evolved its organizational structure through several stages, commissioning external evaluations to both review its progress and recommend opportunities to increase its impact.

While the CLEAR Framework appears quite structured, the reality of the systems change process is often messy and ambiguous. Many stakeholders describe the experience of systems leadership as a journey of discovery that evolves over time, leading to moments of discovery or insight—what we describe as ‘Aha! moments’—that crystallize each step of the journey.

Reprinted from Dreier L. et al. (2019) ‘Systems leadership can change the world—but what exactly is it?’ *World Economic Forum*, available at https://www.weforum.org/agenda/2019/09/systems-leadership-can-change-the-world-but-what-does-it-mean/

Box 3.1.7 Systems leadership

Systems leadership: a tool for our times

Systems leadership is a set of skills and capacities that any individual or organization can use to catalyse, enable, and support the process of systems-level change. It combines collaborative leadership, coalition-building, and systems insight to mobilize innovation and action across a large, decentralized network.

Two very different examples illustrate what it can look like in practice. The 2015 Paris Agreement, signed by 195 countries with support from thousands of organizations, was spearheaded by Christiana Figueres, a global diplomat who emphasized practicality, flexibility, and collaboration to bring stakeholders onboard, securing an historic agreement. At a more local level in Richmond, California, a community organizer named Najari Smith founded a new venture called Rich City Rides, galvanizing community members, local businesses, and city government to address the interconnected challenges of employment, health, and environmental sustainability among low-income communities of colour in the city.

These two leaders operated in very different spheres, but they used some similar tactics: combining a deep understanding of the systemic issues they wanted to address; an ability to engage and align diverse stakeholders around shared goals; and an emphasis on empowering action and collaboration by a broad network of organizations.

Systems leaders apply an unusual combination of skills and attributes to mobilize large-scale action for systems change. Like many leaders, they tend to be smart, ambitious visionaries with strong skills in management and execution. Unlike traditional leaders, they are often humble, good listeners, and skilled facilitators who can successfully engage stakeholders with highly divergent priorities and perspectives. Systems leaders see their role as catalysing, enabling, and supporting widespread action—rather than occupying the spotlight themselves.

Resonant leadership

This reflects the type of modern leadership required to deal with the unprecedented changes affecting our physical and social environments. Political, economic, technological, and social change are driving profound transformation in our organizational models making predictability and stability elusive if not impossible. The sheer complexity of our organizations has increased resulting in confusing organizational structures the global connectedness of our practice means that even the simplest organizations are required to reach out and be connected to faraway places. These uncertainty calls for resonant leaders—leaders capable of charting through unexpected territory and inspiring people in their organizations, institutions, and communities. They create opportunities where there are challenges. They move people—powerfully, passionately, and purposefully.

Resonant leaders are in tune with those around them resulting in people working in sync with each other’s thoughts and emotions. They either intuitively understand and use their EI (self-awareness, self-management, social awareness, and relationship management). They manage their own and other’s emotions as well as build strong trusting relationships. Resonant leaders are exciting and get results. EI is a must and great leaders build

resonant relationships around them. Great leaders are emotionally intelligent, and they are mindful—they seek to live in full consciousness of self, others, nature, and society. The face the work of uncertainty with hope; they inspire through clarity of vision, optimism, and a profound believe in there and tier people's ability to turn dreams into reality. They face sacrifice, difficulties, and challenges with empathy and compassion for the people they lead and those they serve.

See Box 3.1.8.

Box 3.1.8 Questions to ask about a resonance in leadership

Is the leader inspirational?

Does the leader create an overall positive emotional tone that is characterized by hope?

Is the leader in touch with others? Does the leader know what is on other's hearts and minds? Does the leader experience and demonstrate compassion?

Is the leader mindful—authentic and in tune with self, others, and the environment?

Leadership development

Leadership development expands the capacity of individuals to perform in leadership roles within organizations. Leadership roles are those that facilitate execution of a company's strategy through building alignment, winning mindshare, and growing the capabilities of others. Leadership roles may be formal, with the corresponding authority to make decisions and take responsibility, or they may be informal roles with little official authority (e.g. a member of a team who influences team engagement, purpose, and direction; a lateral peer who must listen and negotiate through influence).[1]

Leadership development is thought to be key to business success. A study by the Center for Creative Leadership holds that 65% of companies with mature leadership development programmes drove improved business results as compared to 6% of companies without such a programme. Similarly, 86% of companies with leadership development programmes responded rapidly to changing market conditions whereas only 52% of companies with immature programmes were able to do so.[2]

For many public health practitioners, leadership development is both through on-the-job experience combined with formal training opportunities.

The latter often involves training multisectoral teams in an applied, team-based, and collaborative leadership development model. For public health leaders, a focus on leadership core principles, working across sectors, quality improvement principles, and the use of data for planning, assessment, monitoring, and evaluation, and developing the population health perspective are increasingly seen as foundational.

Leadership development places such importance on self and peer evaluation, mentoring and coaching to ensure leaders develop greater self-insight exploring the known leadership skills and behaviours as well as those which are yet unknown, but perceived by others. Without this self-awareness, it will be much more difficult to behave in the way research has shown that good leaders do. This, in turn, will have a direct impact on your colleagues, any team you work in, and the overall culture and climate within the team as well as within the organization, and ultimately the care experience or patients and service users.

See Case Study 3.1.1.

CASE STUDY 3.1.1 Training local teams to be health leaders in poor communities: a case from the Philippines

The Philippines provides an innovative approach to leadership for the health needs of the most deprived and vulnerable populations. Begun in 2002, the Leaders for Health Program (LHP) was predicated on the understanding that health professionals must work in concert with political and community actors if basic health problems are to be addressed in low-income communities. This 'Tri-Leader' approach brought together the community doctor, the mayor, and a local community leader and trained them, both individually and as a team.

To address the need that medical leaders understand and are able to use evidence to inform policy, doctors received postgraduate training resulting in a Master in Community Health Management. Recognizing that the local political and community leaders often did not have an advanced level of education, the programme created a certificate course in community health management tailored to them, but paralleling the master's training provided to doctors. Joint workshops and training sessions were also held for the tri-leaders together. In addition, all three benefited from coaching and mentoring from a more experienced leader of their own category from another part of the country. Once this team began to identify priorities in its locality, the LHP provided assistance in identifying donors for specific interventions. For example, some communities invested in sanitation and clean water systems. One community established a local pharmacy; another invested in a boat for emergency transport of patients.

By taking this innovative approach to leadership—one that recognizes the importance of joint leadership in the medical, political, and local communities in order to address public health needs—the LHP has been able to demonstrate greater success than other initiatives that focus only on placing trained doctors in low-income areas.

Its success would seem to be due to the programme's understanding of the complexity of health systems. For example, addressing water-borne diseases properly requires sanitation systems, and sanitation systems cannot be built without political support.

Community leaders helps doctors to see beyond the narrow biomedical domain to the broader political and sociological setting in which public health problems must be tackled. One mayor reported that earlier attempts to post doctors to his village were unsuccessful because the doctor was perceived to be making demands arrogantly of a resource-poor community, rather than working with the community to reach a common understanding.

A cost analysis of the programme found that the cost per person for the close to 1 million beneficiaries in the 36 towns that participated in the LHP over its initial 4-year period was Philippine pesos 60 or USD 1.50 per year. Furthermore, for every peso invested in the programme as grant, the local government and other national government partners were able to raise a counterpart share of Philippine pesos 1.27. LHP therefore stimulated the mobilization of local resources for health system development. Most of the graduate s of the LHP have continued to work in their posts. Some joined various units of the Department of Health, the US Agency for International Development and Médecins Sans Frontières, showing a remarkable record for retaining health professionals in places of need. As a result of the LHP's success, its expansion to other local government units is now being considered as part of the national effort to strengthen local health systems.

The UK Public Health Skills and Knowledge Framework (PHSKF)

The Public Health Skills and Knowledge Framework was first published as the Public Health Skills and Careers Framework in 2008 through the collaborative efforts of lead agencies in public health across the United Kingdom. The Public Health Skills and Knowledge Framework (PHSKF) has been revised following extensive consultation with the public health workforce and collaboration between lead agencies across the United Kingdom. The revised framework aims to reflect the current public health landscape, ensuring the public health workforce continues to develop the skills and competencies needed both now and in future. The framework is accompanied by a user guide, explaining how it can be used by individuals, employers and educational providers working in public health (Case Study 3.1.2 and Fig. 3.1.1).

Case Study 3.1.2 The Public Health Skills Framework

The PHSKF provides:

- The functional areas in which individuals, teams, and organizations operate to deliver public health outcomes
- Statements that describe what functions an individual might carry out in the course of their work. The combination of functions will vary from individual to individual and from role to role
- A benchmark or single point of reference for the UK workforce and their employers to help individuals plan their own personal development and to help employers to plan and develop their workforce
- A tool to facilitate the generation of job descriptions for new roles; templates for standard roles; and profiles for individual roles
- A common reference for the review and development of standards of practice and curricula for training and education across levels of the qualifications framework
- A description of the public health functions and subfunctions in a way that could be presented through and accessible and easy to navigate digital platform (aka: 'skills passport')

UK Faculty of Public Health Good Practice Framework

Professional bodies including the Faculty of Public Health have published extensively on guidelines for public health practice including: Good Public Health Practice—General Professional Expectations of Public Health Professions (2008) and its application. It has been reviewed and updated as necessary in line with developments in professional practice and other relevant guidance (see Table 3.1.1 and Box 3.1.9). The guidance provides the basis for good professional practice in public health. It applies to all members of the core public health workforce, including public health practitioners and specialists, and those training to become practitioners and specialists.

The standards in this guidance are designed to be complementary to those contained in other professional codes of practice. Doctors regulated by the General Medical Council must meet the standards set out in Good Medical Practice. All other professionals must similarly meet their relevant codes of professional practice.

American leadership courses are outlined in Case Study 3.1.3.

Table 3.1.1 Competencies needed by leaders in public health

Creating change	Influencing politics	Working transorganizationally	Building teams
Visionary leadership Be able to articulate an evidence-based vision of the future and incorporate it into strategy	*Political processes* Determine appropriate actions on policy and political issues, organize key actors to cooperate for regulatory and legislative changes, and translate policies into programmes and services	*Understanding of organizational dynamics* Assess and develop systems structures based on an understanding of culture and organizational behaviour	*Develop team-oriented structures and systems* Change system infrastructure to innovative, learning teams
Sense of mission Facilitate the development of a mission, communicate it, and 'model' it through personal behaviour	*Negotiation* Mediate potential crises, bargain, and co-ordinate with key stakeholders	*Interorganizational collaborating mechanisms* Involve key actors and networks across a broad range of organizations and groups in collaborative coalitions	*Facilitate development of teams* Empower, motivate, and reward teams
Effective change agent Think creatively and analytically about systems and change strategies, and facilitate dialogue and empowerment of others to take action	*Ethics and power* Identify and use alliances based on ethical principles	*Social forecasting* Analyse trends and communicate predictions to consortium partners	*Serve in facilitation and mediation roles* Negotiate and intervene to help teams' function
	Marketing and education Use social marketing and health education to influence key audiences		*Serve as an effective team member* Through own behaviour, 'model' the key characteristics of listening, encouraging, and motivating while displaying integrity, commitment, and honesty

Box 3.1.9 Good Professional Practice Framework

A. Knowledge, skills, and performance: professionalism in public health practice

- You must be competent in all aspects of your work as a public health professional and retain your competence throughout your working life
- You must recognize and work within the limits of your competence, seeking further advice and consulting with colleagues where this is required.
- You must practice within ethical, legal, and regulatory limits that apply to your area of public health practice.
- You have a duty to monitor, protect, and improve the health of populations.
- You must be satisfied that you have valid authority, including consent w here informed consent is required f or interventions.
- You are expected to improve and develop your practice continuously.
- You must be able to receive and act upon feedback on your practice and performance, both positive and negative.
- You must take care to delegate responsibility to others safely.
- You must keep records of important decisions, actions, and consequences.

B. Safety and quality

- You have a duty to safeguard and protect the health and well-being of your population
- Your duty to vulnerable groups extends to their relatives, carers, and partners.
- You must plan and act in accordance with available evidence and use resources effectively and efficiently
- You must be professional and ethical in your public health practice at all times.
- You must make sure that you and other professionals are able to be professional and ethical in your and their public health practice.
- You must maintain financial rectitude in all your public health practice dealings.
- You must declare any relevant commercial or financial conflicts of interests you may have.
- You must not allow your own health and well-being to affect adversely your professional practice.
- You must have in place arrangements to compensate anybody who may suffer as a result of deficiencies in your work or that of your team.
- You must conduct research (including designing, organizing, and carrying out research) with honesty and integrity.

C. Communication, partnership, and teamwork. Collaborative working: organizational community and individual

- You must work in, and manage, partnerships and teams effectively and with due consideration of others.
- You must make sure that relevant information is shared.
- You must make sure information to be shared is meaningful.
- You must respect the right of people to decline to take part in interventions, initiatives, teaching, or research even if it may be of benefit to them.
- You must maintain your focus on the effectiveness of interventions.
- You must treat colleagues, individuals, and communities fairly and with respect.
- You have a professional responsibility to support trainees and colleagues in your work environment, through formal supervision, formal and informal mentoring, and modelling professional public health practice. This includes providing honest and objective assessment of performance and supporting trainees or staff you manage with appropriate levels of supervision.

D. Maintaining public trust: probity and protecting the public

- You must ensure at all times that your standards of practice justify the public's trust in your work, and in the work of the wider public health profession.
- You must disclose professionally facts which may have a bearing on your professional performance.
- You must be vigilant about issues concerning data confidentiality and data protection.
- You must respond to concerns and complaints.
- You must be honest and objective when assessing the performance of those you have supervised, trained, or worked with.
- You must be honest and trustworthy when writing reports, and when completing or signing references, forms, reports, and other documents.
- You must co-operate with legitimate requests f or information from official organizations monitoring public health.
- You must respond, when and where you are able, in emergencies.
- Your advertising of your services must be truthful, honest, legal, and decent.

Case Study 3.1.3 CDC National Leadership Academy for the Public's Health, the CDC Laboratory Leadership Service, and ASTHO Leadership Institute

CDC strives to empower public health professionals with tools to improve public health practice within their jurisdictions. To further this mission, CDC's Center for State, Tribal, Local, and Territorial Support has provided support and partnership to the Public Health Institute's Center for Health Leadership and Practice External to launch and maintain the National Leadership Academy for the Public's Health (NLAPH)External.

NLAPH offers an innovative style of leadership development by bringing together teams of leaders from multiple sectors who actively engage their communities to improve population health

and achieve health equity. This 1-year programme uses blended learning modalities and an action learning process that includes a webinar series, leadership retreat, coaching support, peer networking, an applied health leadership project, and web-based resources. Competencies are embedded within the programme curriculum to encourage the advancement of leadership knowledge, attitudes, and practices.

Programme goals

The goals of NLAPH are to:

- Educate stakeholders about evidence-based policy options
- Drive the adoption of evidence-based practices in communities
- Better align medicine and public health
- Improve health outcomes in our nation through sustainable systems change

The objectives of NLAPH are to

- Provide ongoing leadership training and support to leaders that work across sectors to address community health issues
- Improve leadership teams' capacities to apply continuous quality improvement methodologies, measure progress of the projects, and document the impact of leadership development
- Build and support the development of communities with multisector leadership learners using online technology and social media tools that will contribute to community health improvement goals and inform policy change

Curriculum

Each community-based team receives leadership training and coaching from national experts and through collaboration with other teams via retreats, webinars, networking, an applied health leadership project, and web—based resources.

Competencies: Advance the leadership knowledge, attitude, and practice of individuals and teams to lead systems change efforts including the following components.

- Individual leadership mastery
- Ability to work effectively across sectors and with diverse stakeholders
- Community organizing and advocacy
- Leveraging resources for collective impact
- Policy analysis and development
- Commitment to health in all policies, social determinants of health, and advancing equity.

Four work phases of the NLAPH year:

- Inspiration
- Ideation
- Implementation
- Growing, sustaining, and transition

CDC Laboratory Leadership Service LLS

The CDC Laboratory Leadership Service (LLS) was launched in 2015 and develops laboratory scientists who integrate safety and quality as principal elements in their work, which is vital to protecting the public's health, safety, and security. CDC's LLS fellowship programme prepares high calibre PhD scientists to become public health laboratory leaders. Through on-the-job service at CDC and other public health laboratories, fellows acquire and apply skills in laboratory quality management, the science of biosafety, and leadership.

In this two-year competency-based experiential learning programme, LLS trains fellows in laboratory quality management, the science of biosafety, leadership, and other critical skills—building a strong foundation for future public health laboratory leaders.

LLS is closely aligned with CDC's Epidemic Intelligence Service (EIS) to promote interdisciplinary training, applied learning, and networking between laboratory scientists and epidemiologists. LLS provides opportunities for fellows to serve public health agencies and learn through field experiences and domestic or international emergency responses.

CDC's guiding principles for laboratory work are to ensure the safety of all staff and the community and be as transparent as possible about our work as we conduct high-quality scientific research to protect people in this country and around the world.

LLS was established as one of the multiple improvements to lab safety practices and procedures across the agency, with the goal of increasing CDC's culture of safety. As such, the core competencies of the LLS fellowship programme are designed to instil excellence through training and education in laboratory quality management, the science of biosafety, and leadership. The LLS programme's Core Activities of Learning are based on competencies published by CDC and Association of Public Health Laboratories (APHL).

LLS fellows learn through on-the-job experience, classroom instruction, case studies, exercises, and e-learning. Throughout their fellowship, LLS fellows:

- Learn skills in and apply public health laboratory competencies—particularly those focused on biosafety, quality management systems, and management and leadership—as they approach real world public health scenarios
- Begin training in July with an intensive, 1-month orientation in Atlanta, Georgia
- Attend a one-week in-person training each fall of the fellowship
- Participate in brief monthly trainings
- Have access to many other optional training opportunities that they can take based their needs
- Learn about and have access to CDC-specific tools for literature reviews and data analysis (including tools for bioinformatics and informatics)
- Obtain education through hands-on activities under mentorship and guidance from host site laboratory supervisors
- Present findings from investigations and studies during regular seminars and annual conferences
- Attend trainings, conduct investigations, and network with EIS officers and other CDC fellows

LLS fellows' learning is based on competencies published by CDC and APHL and achieved through the programme's Core Activities of Learning:

- Conduct applied laboratory research to address a public health or safety-related issue.
- Conduct a safety risk assessment to evaluate the probability and potential consequences of exposure to a given hazard.
- Evaluate a quality management system.
- Incorporate bioinformatics principles into applied public health laboratory science.
- Give a 10–20 minute oral presentation to a scientific audience.
- Give an in depth public health talk on the fellow's original LLS work or field of study.
- Write and submit, as first author, a scientific manuscript for a peer-reviewed journal.
- Participate in laboratory operations management.
- Communicate complex scientific concepts to an external lay audience.
- Provide service to public health laboratories.

ASTHO Leadership Institute

The ASTHO Leadership Institute (ALI) is a year-long, cohort-based leadership development programme designed to enhance the success of new state and territorial health officials (S/THOs).

In partnership with experts in executive leadership development, nationally recognized public health leaders, and experienced S/THOs, ALI offers a customized learning programme which includes opportunities for self-assessment; development of knowledge and skills through intensive retreats; access to a learning management system with on-demand tools and information; executive coaching; and formal mentorship by experienced S/THOs.

The leadership competencies in the framework provide a good example of the activities associated with leadership in relation to different groups, situations, settings, and intentions. All leadership stems from the ability to drive one's own actions and conduct. This area then describes action to lead and manage others; change systems; and finally around setting strategic vision and establishing collective buy-in and ownership.

The NHS Leadership Framework

The Healthcare Leadership Model has been developed by the NHS Leadership Academy, working with the Hay Group and colleagues from the Open University. It is an evidence-based research model that reflects: the values of the NHS; what we know about effective leadership; what we have learnt from the Leadership Framework (2011); and what our patients and communities are now asking from us as leaders (Box 3.1.10).

The NHS Leadership Framework (LF) provides a consistent approach to leadership development for staff in health and care irrespective of discipline, role, or function, and represents the foundation of leadership behaviour. It sets out a single model of leadership for all health and care staff to aspire to. The LF is based on the concept that leadership is not restricted to people who hold designated leadership roles and where there is a shared

responsibility for the success of the organization, services, or care being delivered.

Box 3.1.10 NHS leadership qualities framework

Cognitive capacities: general intelligence, judgement/decision-making skills, organizing skills
Social capacities: social intelligence/sensitivity, communication skills
Personality: extraversion, conscientiousness, openness, agreeableness, neuroticism/emotional stability
Motives: dominance, drive/purpose, energy, tenacity/persistence
Core beliefs: self-evaluation: self-confidence, self-efficacy
Knowledge: knowledge of the business/sector

The Healthcare Leadership Model is made up of nine ‘leadership dimensions’. Research has shown that all nine dimensions of the model are important in an individual’s leadership role. However, the type of job they have, the needs of the people they work with, and the context of their role within their organization will all affect which dimensions are most important for them to use and develop. It is also important to realize that areas identified for development within the model may be as much about how you manage yourself as about how you manage your behaviour and relate to other people.

The intention therefore is not that this model is ‘set in stone’ and will still be appropriate for healthcare staff in 2023. Instead, the intention is to make ongoing updates to the model, to make sure it remains as relevant to staff in 2 or 5 years’ time, as it is to them today. This more flexible and innovative approach will result in future versions being available over the next few years.

Leadership across the lifecourse

There are many paths to leadership in public health. Many leaders first entered the profession with a strong desire to serve. Through the course of their careers, they were exposed to circumstances that deepened their commitment. Frequently, they sought out challenging circumstances in which to gain much needed experience. They travelled, engaged in development work, often involving poor countries and communities. In the

course of this exposure, they took up more advanced public health studies, perhaps did some research, wrote articles in scientific journals, or managed a healthcare facility. Some had long periods of service in their own country before being exposed to international work. For others, international exposure came early, usually through some clinical or public health training abroad.

Some public health leaders enter the field after years of working in the clinics, practising a specialty like paediatrics, obstetrics, or surgery. Others come into positions of leadership through the field services, rising through a public health organization, or a non-governmental organization. Others were involved in academia, teaching, and research, consulting, or working with a development agency. Public health leaders could also have been involved in politics. Or they could once have been cause-oriented activists, involved in issues such as HIV prevention and primary healthcare.

Central to the growth and development of public health leaders are the years when he/she developed the personal qualities of self-awareness, self-belief, and self-management. For many leaders, their involvement in public health was imbued with higher purpose and even that they were instruments of a higher power to do good work. A desire to continue learning new things was often mentioned as a source of great satisfaction. Here are a few things you can do to choose and develop your own authentic and effective leadership style.

Plan for life-long investment in leadership development

One pursues leadership by steadily inculcating in oneself the personal qualities, competencies, and principles that make up a true leader. One does not acquire these necessary attributes and skills simply by ascending to a leadership position, often via political patronage, especially if one lacks adequate preparation. Study, training, reflection, exposure, and experience are all elements of this preparation. Thus, as one’s leadership traits flourish, the time will come when one is ready to assume a leadership position. Leadership should be sought in this way from day one of any career and hence, any strong public health organization should encourage leadership development at all levels.

Envision your future self

Public health remains an fascinating career choice with a variety of options for leadership throughout one's career. Whether deciding to work in academia, service public health, or a combined approach; working at different levels within the health and care system (e.g. global, national, regional or local); or subspecializing within particular public health disciplines (e.g. global health, epidemiology, health improvement, health protection, health inequalities). Understanding your strengths, passions, commitment to ongoing learning, maximizing opportunities for progression, and ensuring you have a strong network of professional support should all be taken into consideration when developing your 5 or 10 year career goals plans.

Similarly, one should take time to explore what kind of leader you would like to be, in which setting, and for what purpose: What kind of leader do you want to be? How would you be most effective as a leader? Who are the current system leaders you admire and why? What kind of leadership style would be of the most benefit to your organization, and would allow you to be the best leader you could be?

Committing to single leadership style isn't the only way to look at leadership. Most real leaders use a combination of styles, depending on need, situation, context, and desired outcomes. You can adapt most styles to most situations, but always remember to align these the real needs of the organization. You may need to practice a different style at the beginning from the one that you want to assume over the long term, in order to solve problems in the organization, or to get people on board. The most important practice is that you are continuously reviewing, learning, practising, and refining your craft.

Know your values and guiding principles

Individual context, culture, and background dictate how each leader will interpret their own organization's principles and will complement them with their personal values derived from their personal philosophy of life. Together, this collection of values and principles will serve to give focus and meaning to the health leader's work.

For example, PHE has defined its core mission as 'working 24/7 to protect and improve the nation's health and reduce health inequalities'. The agency in turn guided by a number of specific aims including keeping people safe,

working to prevent poor health, working to narrow the health gap and support a strong economy. The way, PHE achieves this by working as ‘One PHE, making the best possible use of the expertise and commitment of our people to deliver the biggest impact and best value for the taxpayer and our partners. We perform five key roles within the public health system, which are underpinned by a commitment to incorporate the reduction of health inequalities into all areas of our work’. Similarly, the International Association of National Public Health Institutes links and strengthens the government agencies responsible for public health. Their mission is to ‘improve the world’s health by leveraging the experience and expertise of its member institutes to build robust public health systems’.

These and other similar organizational values and principles must be understood and embedded firmly in the leader’s mind. And most importantly leaders need to understand the own personal values and principles and how they might intersect positively or negatively with their organization. Leaders need to think and act on their feet. Unless one is sure of one’s values and principles, in a time of crisis, panic and uncertainty might take over. There will not be time to think about remembering your principles when the need to make a decision is immediate. For this reason, taking the time to understand what guides oneself, whether through leadership development, coaching, or mentoring, is invaluable.

Seek mentors

Both the literature on leadership and the practical experience of today’s health leaders underline the crucial importance of mentorship in the development of the complete public health leader. Being prepared to learn from superiors, fellow colleagues, friends, and public figures is essential, however, there is no fixed prescription for mentorship. Ideally, a mentoring relationship should be mutually beneficial, with both parties learning from one another, enriching their understanding of their work and purpose.

By its very nature, mentoring is a personal arrangement between two parties. The mentoring relationship can be formal and structured, with regular meetings and logbook entries; or it could be more informal and sporadic, with the occasional chat over coffee or e-mail correspondence. The opportunity should be taken for the mentor to impart advice, the mentee to report on recent events, and for both to share thoughts on work and even

wider aspects of life, particularly if relevant to a career in health and leadership.

Pursue leadership, not the leadership position

The trajectory of an individual's path to leadership can rise steeply or gently. It is one's willingness to step forward, given one's self-awareness and knowledge of the prospective job, however incomplete, which might mark a person's readiness to lead. A potential leader will almost always be selected by having already demonstrated leadership and by showing readiness to lead. In deciding if one is ready to assume the responsibility of a public health leader, it of course helps to discuss the opportunity with mentors, co-workers, and family members.

Many public health leaders can often point to their 'stepping up to leadership roles' for as long as they can remember, while some others have taken what they have described as a circuitous, organic, and emergent, though no less determined path. A resolute focus on the outcome, being an effective leader, while being open to you route and opportunities for getting there, with regular check-ins with self and mentors, provide the most practical, implementable, and manageable choice for many.

Keep learning and developing your craft

Once in a leadership position, the leader must keep learning, whether updating technical competencies, leadership and management techniques, or investing in one's personal and emotional development. The reality is that the work environment, context, challenges, and opportunities change rapidly and it is imperative that leaders invest in their own continuing professional and personal development to improve their effectiveness, acquire new sills, and strengthen their own resilience.

Throughout the course of one leadership career, mistakes will be made, disappointments and conflicts will occur. The strong face of leadership is easily and well observed, and when times are challenging leaders must dig deep into themselves to find internal resources of strength. The capacity to affirm self-belief and overcome self-doubt is an important ingredient in surviving the difficult times. Strategies include simply pausing to reflect, listening inwardly, and reflecting on thoughts, actions, and lived experience

in the midst of complexity, adversity, and uncertainty. By learning to be truly honest with oneself and seeking objective, constructive, and critical feedback from others, a leader can begin to find an answer to this question and sustain self-improvement. In addition, a leader can and should turn outward to others for strength, listening closely to what the boss, advisors, mentors, spouse, colleagues, friends, constituencies, or even opinion surveys say.

Managing the challenges of leadership

Leadership constantly presents challenges to a leader and their abilities. These challenges are an encouragement to rise to another level, to test oneself and improve in the process, and show that you can accomplish something that may seem difficult or even impossible. Being a leader is in itself a challenge. The challenges of leadership may be viewed as being external, coming from people and situations; internal, stemming from within the leader himself/herself; and those arising from the nature of the leadership role.

It’s almost impossible to imagine a situation where a leader doesn’t have to cope with external challenges. Many public health organizations grapple with lack of funding and other resources, working with political colleagues, dealing with advocates, communicating with, and engaging the public effectively, often while dealing interpersonal problems within the organization. Social, economic, and political forces in the larger world can affect the organization as well. To some extent, the measure of any leader is how well he/she can deal with the constant succession of crises and minor annoyances that threaten the mission of his/her group. If he/she is able to solve problems, take advantage of opportunities, and resolve conflict with an air of calm and a minimum of fuss, most of the external issues are hardly noticeable to anyone else. If the leader doesn’t handle external challenges well, it is likely the organization won’t either.

While leadership presents to each of us the opportunity to demonstrate the best of what we are, it also exposes our limitations. In many cases, good leaders have to overcome those limitations in order to transmit and follow their vision. Fear, lack of confidence, imposter syndrome, insecurity, impatience, and intolerance all act as barriers to effective leadership. At the same time, acknowledging and overcoming them can turn a mediocre leader

into a great one. It's often very difficult for people, especially those who see themselves as leaders, to admit that they might have personality traits or personal characteristics that interfere with their ability to reach their goals. Part of good leadership is learning to accept the reality of those traits, and working to change them so they don't get in the way.

Real leadership makes great demands on people. As a leader, you are responsible for your group's vision and mission, for upholding a standard, often for being the group's representative to the rest of the world and its protector as well. These responsibilities might be shared, but in most organizations, one person takes the largest part of the burden. A common challenge for executive leaders is burnout. The process of giving ourselves, continuously and often in excess, leads us to become ineffective. Over time and if unchecked, the physical and emotional toll on leadership limits our ability to sustain high performance. Many people cope with stress by developing defensive routines—bad habits that keep us in denial about what is really going on inside us and around us. While others have developed strategies to cope and be more resilient, including being physically active, learning, and paying attention to their emotional and spiritual well-being. Finally, organizations, through their investment in workplace learning, workplace well-being, mentoring and peer support programmes, and early referral to support services if required, can create more positive environments to support the well-being and effectiveness of their leaders and managers.

Developing your authentic leadership journey

So thus far, this chapter has explored the definitions and concepts of leadership, explored different leadership styles, introduced frameworks for leadership training and capacity building, and discussed strategies for developing one's leadership skills across one's career and indeed the life course. This final section discusses the concept of authentic leadership—something that leaders are often asked about: How did you discover your passion for leadership? How did you develop your unique leadership voice and presence? How do you stay true to yourself while leading in diverse settings and organizations?

Authentic leadership is an approach to leadership that emphasizes building the leader's legitimacy through honest relationships with followers

which value their input and are built on an ethical foundation. It involves actually holding the beliefs you support; doing and saying what you sincerely believe. To be authentic, one must truly be himself or herself. It's not a switch that gets turned on during the commute to the office; you must be yourself and take responsibility for your behaviour. Generally, authentic leaders are positive people with truthful self-concepts who promote openness. They have the self-confidence and ability to expose their own frailties and weaknesses as well as their strengths and assets, having a genuine passion for what they are doing, caring for the organization's mission and what it means, and the desire to provide value to others, with true and unyielding commitment, absolute integrity.

Start with yourself

Use what you know about your own personality, and about how you've exercised leadership in the past—it is critical to be important to be honest with yourself about who you are. First, be clear with yourself about what your natural tendencies and talents are. Not everyone can be charismatic, but almost everyone can learn to distil and communicate a vision that reflects the hopes and needs of a group. Knowing who you are is the first step towards both choosing a style and understanding what you'll have to do to adopt it. Being truly honest with yourself is difficult—it takes an honest self-assessment, which can mean stripping away defences and facing insecurities. In addition, it may take some time with a coach, mentor or a trusted friend, or hearing feedback from colleagues and co-workers.

Becoming an authentic leader is not necessarily about learning how to lead authentically. It's about taking what is genuinely there, inside you, and letting it be visible for all to see and experience. Turning into someone you are not while at the office is all too transparent and doesn't help you build the trust and enthusiasm you expect from your staff.

Think about the needs of the organization or initiative

You can adapt most styles to most situations, but don't neglect the real needs of the organization in your calculations. You may need to practice a different style at the beginning from the one that you want to assume over the long

term, in order to solve problems in the organization, or to get people on board.

Authentic leaders are mission driven and focused on results. They are able to put the mission and the goals of the organization ahead of their own self-interest. They do the job in pursuit of results, not for their own power, money, or ego. They also focus on the long term. Leaders realize that to nurture individuals and to nurture a company requires hard work and patience, but the approach pays large dividends over time.

Observe and learn from others

Authentic leaders lead with their heart, not just their minds. They are not afraid to show their emotions, their vulnerability, and to connect with their employees. This does not mean authentic leaders are ‘soft’. In fact communicating in a direct manner is critical to successful outcomes, but it’s done with empathy.

There is much to be learnt from observing leadership behaviours and practices of others—examining what were their styles, and whether they were effective. Find a mentor. If there’s a leader whom you particularly admire, and that person is accessible, talk with him/her about leadership issues—about how they perceive what they’re doing, how they’d handle particular situations and why, etc. How did they handle different kinds of situations? How did what they did make you and others feel? Try to watch others in action and talk to them about how they see what they do. What do you like about how they operate? What don’t you like? What can you incorporate into your own style? Most people, especially if they’re good leaders and conscious of what they do and why, welcome the opportunity to help others develop their own leadership skills.

Use research on leadership

There are lots of resources available on leaders and on both the theory and practice of leadership. They’ll give you a lot more ideas about leadership styles, and help you refine your own thinking about what leadership is and what kind of leader you’d like to be. Finally, remember that the research, evaluation, and policy fields on leadership continue to evolve rapidly and there will always be more to learn. Remember that no matter how well

you're doing, none of us are perfect leaders—it never is, and never will be. Be prepared to find for yourself or hear from others the negative as well as the positive, to consider it carefully and objectively, and to make corrections if necessary. That way, you can not only become a good leader, but continue to be one.

Through ALI, participants have access to national thought leaders and the opportunity to build a trusted network of peers. All programme activities are based on best practices for adult learning and research-based core competencies for success as a chief health strategist. ALI is funded with support from the Robert Wood Johnson Foundation.

Box 3.1.11 Steps for engaging in authentic leadership

Authentic Leadership works on the principle that a leader can prove their legitimacy by nurturing sincere relationships with their subordinates and giving importance to their input.

Authentic leadership involves actually holding the beliefs you support; doing and saying what you sincerely believe. To be authentic, one must truly be himself or herself. It's not a switch that gets turned on during the commute to the office; you must be yourself and take responsibility for your behaviour.

Authentic leaders are usually the first ones to embrace the change they espouse, setting the example for others. They are visionaries who go against the grain to do what's best for their organization because it's truly in their heart.

Authentic leaders have integrity. Many people can lead, but only authentic leaders can do so with the values, morals, and integrity of a strong character. People know and feel this strong character and are drawn to it. People trust, respect, and listen to authentic leaders, making it easier to lead.

Authentic leaders create communities at work; communities that work. They foster friendships among and between co-workers to link humans to one another so they have something else and someone else to work for other than themselves.

Authentic leaders learn about themselves to foster excellence in themselves and the organization. No one is perfect and to hold perfection on a pedestal, whether it be personal, a department, or the whole organization, is setting up for failure. Instead, authentic leaders strive for excellence and use failures and mistakes as a way to gain wisdom and to move forward.

Getting the public health leaders the world needs

We need public health leaders everywhere and at every level of the health system. However, good leaders are most needed in places where people are poor and suffering simply because there is such a scarcity of them there.

Committed and effective leaders often provide the vision and impetus to mobilize people and resources in needy areas. How can the international health community help developing countries develop the needed leaders?

A good starting point is to aim at strengthening educational institutions, which can provide relevant, team-based training. Schools of public health have an important role to play (Colgrove et al. 2010). Helping governments and their partners to improve public health working conditions, including financial and non-financial incentives, will also help to attract and retain talented people. From an international perspective we can work towards empowering nations to do this self-sufficiently, strengthening their own frameworks for leadership.

Health leaders have used the term ‘capacity release’ in reference to this kind of endeavour (Chan 2007). It must be stressed that training programmes are only one component of a comprehensive approach that should include strategies to retain promising public health workers and sustain the idealism of leaders who are prepared to venture forth to places of hardship. We must encourage and support them to stay where they are most needed. Examples of work being done on this include the WHO framework on training leaders and managers (Egger et al. 2005) and related work to strengthen leadership at all levels of the health system.

The challenge now is particularly great. We have not yet established systematic ways to develop public health leaders, while the context is becoming ever more complex. To address the social determinants of health, confront the ongoing communicable disease burden as well as the rising burden of NCDs, and truly ensure ‘health in all policies’ will require devoted and determined public health leaders at all levels of society and in all sectors.

Conclusions

This chapter has focused on strategies for developing, promoting public health leadership. As we reach the end of this chapter, there are some key points for the aspiring leader: Leadership is manifested in a complex and dynamic interaction between the leader, the followers, and the context. Parables about different types of leadership illustrate the diversity of contexts and behaviours that may be associated with successful leadership.

Leadership style is the way in which a leader accomplishes their purposes. It can have profound effects on an organization and its staff members and can determine whether the organization is effective or not. Leadership style depends on the leader's and organization's conception of what leadership is, and on the leader's choice of leadership methods. Depending how those fit together, a leader might adopt one of a variety styles, each reflected in the way the organization operates and the way its staff members relate to one another.

In the face of ever-increasing complexity, public health leaders are needed to prevent, treat, and eliminate disease and promote the health and well-being of all people. Such leadership can be developed and provided by local, national, and international actors. Public health leaders demonstrate personal qualities and skills, underpinned by fundamental principles, which enable them to influence actions and results. The constant manifestation and practice of these attributes and beliefs is a continuing challenge in a leader's job and career.

In closing, everyone's 'path to leadership' is unique, personal, and never-ending. However, being proactive; actively seeking out opportunities to lead; investing in life-long training, coaching, and mentoring; and understanding your personal values, mission, and life purpose are all essential parts of the personal development process. Stepping up to answer to the call to lead, and pursuing activities to develop your leadership skills, although sometimes challenging is nevertheless a privilege that should engage the mind, the heart, and spirit. It is a stimulating, rewarding, and never-ending quest. We bid the reader all success.

ACKNOWLEDGEMENTS

The authors would like to thank Amimo Agola, Anand Kurup, Chadia Wannous, Christine Lamoureux, Claudia Vivas, Delanyo Dovlo, Dick Chamla, Francis Omaswa, Guangyuan Liu, Helen Robinson, Lealou Reballos, Maria Eufemia Yap, and Miriam Were, among others, for their insights into the issues of leadership in public health. The authors would also like to acknowledge the contributions of Carmen Dolea, Daniel Shaw, and Joanne McManus to an earlier version of this chapter.

3.2

Ethical principles and ethical issues in public health

Nancy Kass, Amy Paul, and Andrew Siegel

Medical ethics, bioethics, and the emergence of public health ethics

While some cite the Hippocratic Oath as the first articulation of moral duties of physicians, and others cite John Gregory or Thomas Percival as giving birth to medical ethics, codes, and teachings about moral duties of physicians have existed for hundreds, if not thousands, of years (Percival 1985; McCullough 1998). Medical ethics focuses primarily on physicians' interactions with individual patients and is the focus of significant scholarship. The American Medical Association has longstanding codes of medical ethics, and instruction on medical professionalism is nearly universal in US and Canadian medical schools (Kao et al. 2003). The American Association of Medical Colleges requires that principles related to medical ethics should be taught in medical core curricula (Allen 2007); the UK General Medical Council requires medical schools to teach medical ethics; and the Medical Council of India requires students to 'observe medical ethics' as part of exemplary behaviour (Ravindran 2008).

Bioethics emerged more recently, with a broader focus. 'Bioethics' as a field arose in the 1960s and 1970s (Walter and Klein 2003) arising from questions of resource allocation, moral questions raised by new reproductive and genetic technologies, a growing patients' rights movement, and a lack of oversight in human subject research. Important scholarship grew, and a national commission was convened in the 1970s to examine questions of human research ethics. The National Commission drafted the Belmont Report (National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research 1979) delineating three ethics principles for human research—beneficence, respect for

persons, and justice. This early work in bioethics not only went beyond the individual doctor–patient dyad but also informed public policy.

Bioethics ignited. Centres were created, journals started, meetings convened, and professionals from various disciplines started calling themselves 'bioethicists'. The three 'Belmont principles' became the foundation for a widely used bioethics text (Beauchamp and Childress 1979). While some suggested alternative approaches, 'principlism' remains a widely used framework for healthcare and research ethics (Clouser 1995; Jonsen 1995; Pellegrino 1995), and Belmont principles were adopted for the Council for International Organizations of Medical Sciences (CIOMS) international ethics guidelines (CIOMS 2002).

Early framers of these principles suggested no principle, a priori, should have moral superiority over any other (Beauchamp and Childress 1979). Nonetheless, issues animating bioethics early on—the need to tell patients and research participants the truth and the right to refuse medical care or research participation—were ones where respect for autonomy, perhaps given too little moral attention previously, was given pre-eminent moral status (Callahan 1984; Pellegrino and Thomasma 1988; Steinbock 1996). Informed consent, an application of the autonomy principle, became a hallmark of the new bioethics. Codes of ethics for clinical practice, which previously focused on not harming patients, added requirements to respect patients' right to decide about their own care (American Medical Association 1990).

The subfield of *public health ethics*, articulated as such, did not appear significantly in the literature until the 1990s, although Marc Lappe had a chapter 'Ethics and Public Health' in the 1986 Maxcy-Rosenau text *Public Health and Preventive Medicine* (Lappe 1986).[1] This chapter outlined core public health ethics challenges: fair distribution of resources, rights of individuals versus groups, and promoting efficiency while recognizing the 'special standing of those who are disadvantaged in terms of their health status' (Lappe 1986, p. 1875). Moreover, Lappe asserted that whereas medical ethics is more concerned with individual autonomy and duties of single health professionals, public health ethics focuses more on equity and efficiency. Lappe suggested individual rights can be compromised for community interests, but only with proportionality—an intervention's benefit must outweigh its harm, and the absolute level of infringement must be minimal. Related, since many public health programmes do not grant

individuals right of refusal, there must be evidence that programmes will provide the good promised. He suggested an inevitable tension between utilitarianism and justice with an ethic of public health capturing the urgency for efficiency, while recognizing the special standing of those in greatest need.

An additional exception from this early history is Dan E. Beauchamp's work, suggesting social justice and communitarian traditions should drive public health (Beauchamp 1976b). While public health practitioners had recognized, for more than a century, the relationship between social conditions and health (see Fee 1977),[2] Beauchamp's work suggested a new idea *within bioethics* that exclusive attention to individual interests, particularly through market justice, will hinder protecting the public's health. Rather, public health should 'require thinking about and reacting to the problems of disability and premature death as collective problems of the entire society' (Beauchamp 1976b, p. 9).

Furthermore, Beauchamp challenged bioethics to see public health as furthering community interests in terms of shared commitments we have to one another. Through collective actions in health and safety, for example, we share commitments to the common life (Beauchamp 1985, p. 34). While Beauchamp did not use the words 'public health ethics', his work is foundational in putting forward the idea that public health has its own set of moral priorities.

By the early 2000s a need for a more structured way to examine ethics issues in public health surfaced, and literature examined how public health ethics issues differed from those in medicine or other areas of bioethics. In 2001 and 2002, four articles were published defining the territory of public health ethics and/or offering tools and frameworks for its analysis (Kass 2001; Callahan and Jennings 2002; Childress et al. 2002; Roberts and Reich 2002), suggesting public health ethics requires identifying programme goals, determining effectiveness, minimizing burdens, proportionality, furthering social justice, and ensuring procedural justice. Publication of the first code of ethics by the American Public Health Association, an organization that had existed since 1832, followed in 2002 (*APHA Code of Ethics*; American Public Health Association 2002).

Ethics and health promotion

In the 1970s, several scholars began addressing the degree to which governments should regulate personal behaviour to promote public health. While many of the discussions were influenced by John Stuart Mill's view that government restrictions on an individual's liberty are justified only to prevent harm to others (Mill 1869), debates ensued over whether interventions to improve the health of the person targeted could be morally acceptable. Daniel Wikler suggested that promoting certain lifestyles conveyed a set of moral values when 'It is not self-evident that this vision of a safe society, with its lack of immoderation, stress, and risk-taking, is to be favoured over others whose constitutive elements have incidental adverse effects upon health' (Wikler 1978a, p. 231).

Edmund Pellegrino, one of the 'fathers of bioethics', described an ethics of prevention (Pellegrino 1981). Preventive interventions, he suggested, ranged from more voluntary approaches like health education to increasingly less voluntary ones like opinion manipulation through mass media, tax and insurance incentives and disincentives, and legal prohibitions in the name of what some consider to be 'the good life', highlighting that we are forced to make decisions about what constraints we will accept to further the common good.

Faden and Faden, similarly, described interventions ranging from facilitation to persuasion to manipulation to coercion, arguing the acceptability of different approaches rests on how rational and resistible they are (Faden and Faden 1978). Described here, to be cited frequently throughout future public health ethics writings, was the concept of *proportionality*: the burden posed by (particularly non-voluntary) interventions should be low and benefits high. As such, incentives should be favoured over disincentives, education favoured over manipulative messages, and government intervention ought not occur without considerable evidence about effectiveness.

The Society of Public Health Educators' code of professional ethics went further, calling voluntariness the *only* acceptable approach, suggesting health educators should 'empower individuals to adopt healthy lifestyles through informed choice rather than by coercion (Society for Public Health Education n.d.).

Purely voluntary interventions do not always work, however (Glanz et al. 1997; Roter et al. 1998), and the question for ethics scholars became whether or under what conditions more controlling interventions were

acceptable. Furthermore, since governments would be implementing stricter measures, how could one ensure their agenda related to public health rather than politics? (Faden 1987). Involuntary measures also assume ‘a benign, wise, and responsive government, something history finds singularly rare’ (Pellegrino 1981, p. 375).

Dan Beauchamp suggested shifting focus from the degree to which governments can regulate individual behaviour to, instead, the legal authority of public health to regulate behaviour of those marketing and distributing harmful products (Beauchamp 1976a). Wikler similarly suggested that if outside influences encourage an individual to alter his or her preferences unknowingly, this diminishes the autonomy with which those choices are made (Wikler 1978b). Coercive measures may be needed to control the manipulation of messages that run counter to the interests of public health.

The rise of chronic disease has more recently shifted the focus of public health ethics back to the acceptability of different types of behavioural interventions or public policies designed to influence behaviour. The high burdens of tobacco-related illness, injury, obesity, and diabetes have prompted interventions that target environmental, behavioural, and lifestyle determinants. In obesity prevention, for example, public health ethics must consider the justifiability of government action to restrict access to unhealthy products such as sugar sweetened beverages in various programmes or institutions as well as the effects such proposals would have on morally relevant values such as liberty, privacy, and fairness. Ethics debate surrounds whether all consumer choices constitute protected liberties, and when, if ever, restrictive policies are justifiable absent direct threats to others.

Infectious disease and public health ethics: HIV and pandemic preparedness HIV/AIDS

Few challenges have forced examination of ethics and public health as much as HIV/AIDS. Multiple public health ethics tensions surfaced, from societal rights versus individual liberties to justice and healthcare access, and arose in core functions of public health: surveillance, disease reporting, containment, and resource allocation. As policymakers navigated tough

decisions, much bioethics literature emerged, influencing what would soon be called public health ethics. Arguably, it was HIV that introduced many bioethics scholars to the world of public health.

In 1983, the Public Health Service (PHS) recommended that gay men be discouraged from donating blood (Centers for Disease Control (CDC) 1983), and soon policy documents and individual scholars examined ethics in HIV policy (Bayer 1983; Institute of Medicine 1986; Presidential Commission on the Human Immunodeficiency Virus Epidemic 1988). Fear and uncertainty precipitated proposals from tattooing infected persons to full quarantine that were highly restrictive while having little evidence of efficacy. Despite almost uniform rejection from bioethics and legal communities (Gostin and Curran 1986; Koop 1986; Macklin 1986; Musto 1986; Porter 1986), policy proposals continued to recommend exclusion of HIV-infected persons from employment, housing, insurance, and school. Bioethicists jumped into the fray to help articulate appropriate public health response and put forward ethical requirements for new screening programmes (Bayer et al. 1986; Childress 1987; Gostin and Curran 1987; Gostin et al. 1987; Hunter 1987; Bayer 1989), cognizant of the tension between potential public health benefits and concerns of exposing at-risk individuals to stigma with no treatment in return.

HIV renewed interest in the ethics of other tools of public health with calls for mandatory HIV reporting, contact tracing, and partner notification. Proponents suggested mandatory reporting would improve understanding of the disease and target education and potential treatments. Critics argued education and treatments could be provided without reporting, which was an unjustified invasion of privacy, particularly when strong antidiscrimination laws did not exist; concerns existed that at-risk individuals would avoid testing, fearing consequences. Support for mandatory reporting increased when treatments became available. HIV stimulated ethics debate in almost every area of public health including health education, duty to treat, resource allocation, access, and financing. While the phrase ‘public health ethics’ was not yet used, the foundation of the field had been laid.

Pandemic preparedness

The re-emergence of pandemic disease in the 2000s pushed public health ethics thinking to modify frameworks for the pandemic context. While the infectious nature of pandemic flu raised familiar tensions between individual interests and population health, the urgency and potential for insufficient resources highlighted additional challenges. Avian flu and severe acute respiratory syndrome outbreaks, for example, were met with insufficient healthcare workforce, vaccine shortages, and complex global governance challenges when pandemics crossed borders, raising questions of healthcare worker obligations, fair resource allocation, and justifications for restricting liberty interests (Gostin 2004; Kotalik 2005). Resulting ethical guidance (University of Toronto 2005; Thompson et al. 2006; CDC 2007, 2011) offered principles for a response while acknowledging the importance of procedural values including reasonable and evidence-based decision-making, inclusivity, transparency, and accountability.

Pandemic influenza also renewed focus within public health ethics on resource allocation as questions arose concerning how best to allocate scarce vaccines, hospital beds, ventilators, and everyday supplies. The US National Vaccine Advisory Committee and Advisory Committee on Immunization Practices recommended giving priority to those in greatest medical need (US Department of Health and Human Services 2005), some asserted priority be given to those in whom we have invested some societal resources, yet who have not had opportunity to experience multiple life-stages, meaning young adults would be prioritized above infants (Emanuel and Wertheimer 2006), others underscored the importance of considering vulnerable populations in allocation (Uscher-Pines et al. 2007; Rosoff and DeCamp 2011; DeBruin et al. 2012), and some emphasized the importance of securing access for those with important roles in maintaining societal functioning and infrastructure (Kass 2001). Questions of resource allocation in a pandemic prompted procedural interests in public engagement as a strategy to incorporate public input into policy decisions (Bailey et al. 2011; Vawter et al. 2011).

Ethical issues raised by recent global epidemics

Ebola epidemic (2014)

Localized epidemics of an haemorrhagic fever caused by the Ebola virus have been reported in central Africa previously, but usually involved no more than several hundred cases. In February 2014, a large epidemic involving 15,261 patients and causing 11,325 deaths suddenly broke out in three countries of West Africa, including Sierra Leone, Liberia, and Guinea (Gostin 2018; Dalziel et al. 2018). Because the early phase of the infection presents symptoms common to many infectious diseases, the disease is difficult to diagnose until it is well advanced. The case fatality proportion, over 70%, is very high. Because the infection is very contagious, transmitting the virus at low doses, and because of the poor infrastructure in the affected countries, the disease spread rapidly. The extremely high level of infectiousness required health personnel to wear heavy protective gear that created a barrier between them and their patients. Thus, the epidemic presented many ethical challenges that, while they may exist to smaller degrees with other infectious outbreaks, were dramatically heightened in this context.

The high risk of infection and subsequent death raised the ethics question of the limits of moral duty of health personnel to provide treatment, given the significant risk to them and, thus, to their ability to continue to provide healthcare (Dubov et al. 2016; Venkat et al. 2015). This concern had been raised previously in the context of the HIV/AIDS outbreak's early years, and indeed through the centuries when outbreaks of influenza and the plague. In West Africa, many healthcare personnel nonetheless agreed to provide care, and other healthcare personnel from other parts of Africa, and from other parts of the globe, stepped forward. And yet this created a moral obligation for the governments and health systems within the affected countries to provide protective gear and treatment facilities. Because the three affected countries are among the poorest in the world, they were hard pressed to meet this obligation, with an untenable dilemma emerging, at least in the early weeks of the outbreak. This underscored a separate issue of what moral obligation wealthy countries have to assist the affected countries (Royo-Bordonada and Lopez 2016)—although many argued that doing so was not only a compassionate response, but also a rationally self-interested one, given how rapidly outbreaks spread globally.

Further, outbreak sparked discussion about the need for wealthy nations to not only assist in the response, but make longer-term investments in the public health systems of the affected countries (Cancedda et al. 2016; Kieny

and Dovlo 2017,). The absence of adequate surveillance, laboratory, and health information systems in Liberia, Sierra Leone, and Guinea compounded the challenges of responding to and controlling the epidemic. Beyond contributing to the response, the outbreak prompted calls for the global community to make investments that would not only hasten the end of the outbreak, but leave the country better prepared to respond to future threats (Gostin 2014).

The scarcity of medical supplies meant that not everyone could receive treatment, thus the issue of priority (Satalkar et al. 2015; Thompson 2016). Related, ethics questions were raised when ex-patriate healthcare workers who became infected were airlifted to more sophisticated medical institutions outside of the country and, in some cases, were given access to experimental treatments, while healthcare providers from the affected countries who became infected were not provided with similar access. While it was clear that employers from the US and Europe, for example, generally had contracts with their employees that guaranteed them evacuation and high quality medical care should they become sick—and local employers provided no such assurances— this highlighted the longstanding disparities between rich and poor countries as an injustice in the response.

Given the high fatality rate and the lack of effective treatments, there was a surge in development of experimental vaccines and treatments. Vigorous debates focused on whether experimental treatments should be provided to all patients who were ill, or whether experimental treatments should be tested through placebo-controlled trials, with the argument that the traditional testing of experimental drugs would more quickly measure their safety and efficacy (Salerno et al. 2016; Thompson 2016; WHO Advisory Panel 2014). Some suggested that this was a context where adaptive trials made the most sense—changing a randomization allocation scheme based on interim findings and, perhaps, even starting with provision of experimental treatment to all.

That the outbreak was occurring in many remote areas, and spreading within and among households, meant that outreach, education, and community involvement was essential both to disseminate key prevention messages and to hear about new cases, rumours, or fears. (Salerno et al. 2016). And yet, without careful attention to how such outreach was to be implemented, the outreach workers themselves, particularly if they entered

in strange protective suits, could appear frightening at a time of heightened anxiety within communities. Questions emerged about whether and when it was appropriate to remove people from homes to bring to treatment centres that might be poorly equipped and whether and when individuals should be isolated or quarantined, particularly if they would then be shunned by their communities or if there was no way to guarantee food, water, and communication for them (Venkat et al. 2015; Thompson 2016).

Zika epidemic (2016)

The 2016 epidemic of congenital malformations attributable to infection by the Zika virus presented an additional set of ethical challenges. Zika is the only mosquito-borne virus known to cause congenital malformations in foetuses. Risk of neurologic malformations is highest in foetuses infected during the first (55%) and second (52%) trimesters of pregnancy, but is still high in the third trimester (29%) Risk of anencephaly is highest in those infected in the first trimester (Brasil et al. 2016; Honein et al. 2017).

Although the risk of adverse outcome of pregnancy is high (42–85%), 80% of Zika infections result in no clinical symptoms, thus making implementation of appropriate surveillance and identification of at-risk (pregnant) women difficult, especially since the risk is highest in early pregnancy when women may not know they are pregnant. Further, globally. the majority of pregnancies are unplanned. Guidelines were issued for all females of childbearing age; these included wearing long sleeves, using mosquito repellents, limiting travel to Zika-endemic areas, and delaying pregnancy (i.e. barrier sex strategies). While these guidelines are useful, the majority of women globally at risk for Zika infection are poor, poorly educated, likely to live in endemic areas, have little access to repellents on an ongoing basis, and have little control of safe sex due to cultural and religious constraints (Editorial 2016). Thus, the majority of women at risk had little meaningful authority or practical ability to protect themselves and little access to termination of pregnancy should they have chosen that if they became infected.

Absent an effective vaccine, control of the mosquito population is the primary community-targeted intervention. Challenges that are pervasive in public health ethics emerge in terms of whether it is acceptable to provide community-wide interventions, such as spraying, that may be objectionable

to some. Who gets to decide, how great the risk must be for public health officials to make unilateral decisions, and what type of consultation can be implemented, even if not all individuals can be consulted, become key ethics questions in these situations. Vaccination against Zika infection, although not available at the time this chapter was written, is likely to become available, raising the question of who should receive the vaccine. Increased attention is directed to the importance of providing vaccines to pregnant women who have traditionally been omitted from public health vaccination campaigns due to fears of fetal harm, with less parallel attention to the need to prevent both pregnant women and their future newborns from dangerous infections. All vaccines will need to be considered in terms of their risks and their benefits, and the same of course will be true in considering administration for pregnant women.

Measles outbreak (2015)

The epidemic of measles in Los Angeles in 2015 illustrates another set of public health ethics issues. Measles outbreaks in the United States have generally been rare, due to herd immunity—that is, the vast majority of individuals are vaccinated, and thus any cases or exposure are unlikely to result in secondary spread. In general, a coverage rate of over 90% is necessary to assure herd immunity and prevention of a measles epidemic. However, due to misinformation about the safety of vaccines widely available on the internet and on social media, and likely due to little awareness of the dangers that measles presents, many parents have refused to have their children vaccinated. Thus, in a particular region of Southern California, with demographically highly educated parents, the coverage proportion fell well below 90%. And indeed this was possible because, at the time, the state of California had one of the most lenient vaccination policies in the country, allowing exemptions from childhood vaccination for ‘philosophical reasons’, considered to be an extremely low bar. When one index case of an infected child attended Disneyland, thus exposing thousands of people, a measles outbreak occurred in Southern California, which then spread as far as Europe. The California legislature subsequently passed a law mandating full immunizations for children entering school with exceptions allowed only for immunocompromised children or any others for whom it would be dangerous. However, many mothers pressure

their paediatrician to write letters of exception for their child, threatening the attainment of the necessary level of herd immunity. Thus, some schools in California have exception rates as high as 58%, rendering the proportion protected well below the 90+% required to develop herd immunity (Los Angeles Times 13 July 2018a and b). What type of vaccination policy for a state to have is a longstanding and difficult ethical issue. Vaccination is one of the most effective public health preventive interventions, preventing millions of people from having a serious illness through an intervention that poses very little risk. And yet by mandating it, the autonomy of the small number of individuals who might have objected is not being respected, due to the importance of protecting others and the community at large. Indeed, because outbreaks are infectious, and because some numbers of children medically cannot be vaccinated, requiring vaccination is a means of protecting all, and protecting the most vulnerable. It is for these reasons that public health departments across the country generally require all children to be vaccinated as a condition of entering school, camp, or daycare, and allow exemptions only for medical or, in some cases, religious, reasons.

Public health and social justice

Until recently, the more theoretical literature on justice and health focused almost exclusively on issues of access to healthcare and the allocation of scarce healthcare resources. While these remain important and contested areas of inquiry, the epidemiological evidence indicates that healthcare plays a relatively limited role in determining health status (Wilkinson and Marmot 2003). It has long been understood in public health that socioeconomic status (SES) (viz. status as defined by income, education, and occupation) is a major determinant of health, giving rise to significant health inequalities between social groups. Some health disparities are due to material conditions related to poverty, such as poor nutrition and crowded and unsanitary living conditions. But studies over the past two decades suggest that poverty alone does not explain the effects of SES on health. There is a gradient in life expectancy, mortality, and morbidity across all levels of the SES hierarchy (Marmot et al. 1991; Marmot and Shipley 1996). Health inequalities in the gradient that exist in the absence of material deprivations appear to be best explained by psychosocial factors,

such as levels of social support and integration, control in the workplace, and hostility (Marmot 2004). There are also studies that, while controversial, suggest that an individual's health is influenced by the level of income inequality in society as a whole, and not just by her own level of income (Kawachi et al. 1999). Increasing attention to the social determinants of health has given rise to a heightened focus on social justice in public health.

The central social justice issue in the context of public health concerns when health inequalities between social groups are unjust. There are several approaches in the literature to addressing this question, all of which are developed from more general theoretical accounts of distributive justice. Theories of distributive justice identify a metric specifying the good that is sought and a principle for the distribution of that good. The primary metrics include welfare, resources, and capabilities, while the competing principles of distribution appeal to equality, priority, and sufficiency.

Metrics of justice vary, with some viewing health as purely instrumental to the good justice seeks and others viewing health as intrinsic to that good. Instrumentalist accounts include Norman Daniels' view that the value of health lies in its serving to secure equality of opportunity to pursue life plans (Daniels 1985, 2008) and the welfare egalitarian and contemporary utilitarian view that health is valuable insofar as it fulfils individual preferences. Each account is subject to the objection that health has value even when failing to promote these ends. Health seems important even for those near the end of life who have completed their life plans (Brock 1989; Segall 2010); health further can have value where one has a weak preference for it, particularly where the preference is due to an adaptation to conditions under which one has been persistently deprived of health (Sen 2009).

An alternative to the instrumentalist perspective conceives of health as partly constitutive of the ends of justice. Various capabilities theorists have argued that a person's ability to achieve good health is a fundamental capability inasmuch as health is essential to human life and flourishing (Sen 2002; Nussbaum 2006; Ruger 2009; Venkatapuram 2011). Madison Powers and Ruth Faden offer a related but distinct conception, viewing health as one of several dimensions of well-being (which also include personal security, respect, attachment, self-determination, and reasoning) that justice aims to secure. But they privilege the achievement of positive health

outcomes over capabilities to achieve health, both because some individuals (children, in particular) are not well positioned to make free and informed choices about their health and because there are threats to health that may not be within an individual's ability to control (e.g. exposure to environmental harms) (Powers and Faden 2006, 2011).

In assessing whether a given health disparity is unjust, one must turn to distributive principles. On a strict egalitarian account, everyone should, as far as possible, have equal health status. This account has been widely dismissed as it would permit 'levelling down' the health status of some without improving the health of others as a means to achieve equality (Parfit 1998). Alternatively, the prioritarian account permits inequalities where they benefit those who are worst off. John Rawls' Difference Principle, which allows inequalities in income and wealth (among other goods) only where they benefit the worst off, is a prominent example of prioritarianism (Rawls 1971). Daniels has applied this view to health, suggesting that distributing social goods in accordance with the Difference Principle would substantially reduce the steepness of the health gradient (2008). Another prioritarian account gives weight to personal responsibility for health differentials, positing that those who do more to promote their health should be given priority (Segall 2010). Sufficientarians, like prioritarians, are concerned with how persons fare in absolute terms; but they hold that justice should ensure that everyone has enough of the goods essential to living a decent life, without regard to inequalities beyond the sufficiency threshold (Frankfurt 1987). Powers and Faden, for example, maintain that justice demands that everyone have a sufficient amount of health, and that the most pressing health inequalities are those that are systematically accompanied by inadequately met needs in other core dimensions of well-being (Powers and Faden 2006).

Given how many people lack adequate health and how little of the vast social and economic gains to the well-off have been accompanied by gains to the worst-off, following either the prioritarian or sufficientarian views of justice likely would lead to profound improvements in population health. While public health practitioners do not bear primary responsibility for addressing the full range of the social determinants of health, some argue that public health should more explicitly incorporate a social justice orientation. Strategies to do so are of course more challenging, and include monitoring social indicators related to health inequalities to engaging in

community organization and collaborative practices that help promote the structural changes necessary to address the material and psychosocial causes of health disparities (Plough 2005).

Public health research

Literature in ethics and public health research falls into two categories. First, there is literature exploring how public health research can be distinguished, conceptually and operationally, from public health practice (CDC 1999; Casarett et al. 2000; Bellin and Dubler 2001; Amoroso and Middaugh 2003). This literature outlines criteria for when an activity is quality assurance, surveillance, or evaluation versus when it is research requiring regulatory oversight (US Department of Health and Human Services 2009). This growing body of literature recognizes the blurry lines between research and practice in many arenas, including public health, and increasingly questions whether distinguishing research from practice is the most salient approach for ensuring ethical protection (Faden et al. 2013). As more data are available electronically, and with greater emphasis on learning healthcare systems and evidence-based practice (Institute of Medicine 2007; Kass et al. 2013), blurriness between research and practice will only grow larger.

Second, there is literature examining activities that unquestionably are research, but exploring whether public health research is different from clinical research, such that it should be exempt from certain regulatory requirements; literature also has addressed whether ethical challenges differ when entire populations are targeted for research.

Distinguishing public health research from non-research activities of public health

In 1999, the Centers for Disease Control and Prevention (CDC) issued what has become a widely cited document aimed at distinguishing public health research from non-research (CDC 1999). These guidelines were written in response to queries from outsiders whether certain data gathering activities conducted by CDC or by state health departments for public health practice

should be categorized as research (Burris et al. 2003). While the guidelines were written to guide CDC employees in their own work, they have been used more broadly. The document asserts that public health practice can be distinguished from research based on what the primary intent of the activity is. If an activity is designed, primarily, to help a public health department do its job furthering the health interests of a particular community, even if it *also* produces data of more generalizable interest, the activity should be called non-research. Research, the guidance continued, is intended to produce generalizable knowledge, to have relevance beyond the population or programme from which data were collected. Surveillance, then, would be considered non-research when conducted in response to 'lawful state disease reporting or monitoring' activities. In 2001, the National Bioethics Advisory Commission echoed CDC guidance stating that projects *intended* to produce generalizable knowledge must be subject to the oversight provided by the Common Rule (National Bioethics Advisory Commission 2001).

The scholarly literature has echoed many of these concepts, especially that intention to produce generalizable knowledge characterizes research requiring federal oversight. Casarett et al. (2000), by contrast, suggest that activities should be regulated as research if: (1) the majority of patients involved are not expected to benefit directly from the knowledge to be gained and (2) additional risks and burdens exist as a result of wanting findings to be generalizable. Participants in a CDC workshop on practice versus research recommended research oversight to be determined by level of risk, rather than distinguishing based on primary intent (MacQueen and Buehler 2004). Bellin and Dubler suggested activities can be considered non-research if there is a commitment to modify programmes based on collected data (Bellin and Dubler 2001), and a recent framework suggests that the degree to which learning and collecting data increase risks or threaten important interests or well-being should dictate the degree of ethical oversight required, regardless of whether an activity is called research or practice (Faden et al. 2013).

Burris et al. contend that collection of data by government agencies fulfils their mandated functions and should be exempt from federal research regulations specifically because they are conducted by public health departments. They suggest an alternative, internal oversight system be created to ensure that 'human beings who become involved in activities that

increase our knowledge (whether defined as research or not) should be protected' and ensure that data collection activities are conducted in the least harmful, least restrictive, and most respectful way possible (Burris et al. 2003).

Fairchild and Bayer, however, suggest *all* data collection by federal or state governments should be subject to ethical review. While not suggesting institutional review boards (IRBs) necessarily perform this review, they advocate for universal review of these activities (Fairchild and Bayer 2004). With so much non-health data widely used and shared through social media, and through the internet more broadly, questions are emerging going forward about whether views about health privacy will change as the sharing of health data likely also becomes more widespread (Voyena et al. 2012).

Ethical issues raised by public health research

Other literature explores whether ethics issues in *public health research* differ from those of clinical research. Papers from the 1970s and 1980s suggested that certain types of epidemiological studies using identifiable records should be exempt from informed consent requirements (Gordis et al. 1977; Kelsey 1981; Waters 1985). Gordis et al. provide dozens of examples, from identifying the link between cigarette smoking and lung cancer, to the link between high concentrations of oxygen for premature infants and blindness, to the link between oral contraceptives and stroke, illustrating the contributions that epidemiological record review has made to public health and suggesting such methods would be nearly impossible if consent were required (Gordis et al. 1977). More recent literature examines whether and how population-based or prevention research differs in ethically relevant ways from clinical research (Taylor and Johnson 2007). Population-based research may not allow individual participants the opportunity to refuse participation, for example, when studies investigate community-wide interventions, like the impact of health promotion media campaigns in some communities and not others. In such cases, IRBs must confirm that risk to individuals is minimal and public health benefit from the research outweighs concerns imposed by individuals' inability to refuse.

Data are generally collected at the population level without individual identifiers.

Population-based research has the potential to stigmatize identifiable groups if the research targets specific geographic, religious, or ethnic communities, or groups defined by a risk behaviour such as injection drug use or sexual orientation. The potential for stigma and social harms was a prominent concern of genetic research and the launch of the Human Genome Diversity Project in 1991, as entire races and indigenous communities were the unit of interest. Social harms animated a recent case, *Havasupai Tribe v. Arizona Board of Regents*. Stored genetic samples for research ultimately undermined traditional understandings of the tribe's ancestral origin, indicated high levels of inbreeding within the tribal community, and assessed associations with schizophrenia, a highly stigmatized condition within the tribe (*Havasupai Tribe v. Arizona Board of Regents* 2008). While research ethics has traditionally allowed analysis of samples that are not individually identifiable, this case demonstrated that population-based research carries the risk that outsiders might think differently about an entire social group as a result of research findings.

It is then not surprising that population-based research is the origin of both community advisory boards (Strauss et al. 2001; Morin et al. 2003; Quinn 2004) and community-based participatory methods (Israel et al. 1998; Macaulay et al. 1999), strategies designed to include community input into planned research methods and dissemination plans. Challenges remain regarding what is meant by 'community' and 'engagement' in the context of research (Hillery 1955; CDC 1997; MacQueen et al. 2001; Sharp and Foster 2007), as well as determining when community input must be sought, when a community has been fully represented, and how to resolve disputes within communities (Sharp and Foster 2007).

Research in resource-poor settings raises additional ethical challenges, both globally and domestically, and points to why the CIOMS guidelines include sections that other research ethics guidelines do not on incentives, responsibilities when studies are over, and justice. A major controversy erupted in 1997 after US-funded HIV trials in low-income countries tested the efficacy of drugs to prevent vertical transmission of HIV. Studies were placebo-controlled even when an effective, albeit expensive and complex, treatment protocol existed. While some scholars and human rights activists asserted that use of placebo was in clear violation of ethical guidelines,

causing millions of infants to contract HIV (see Lurie and Wolfe 1997), others argued that women in the trials were no worse off by participating in trials, and placebo-controlled designs more validly tested whether locally relevant interventions were effective, to then be implemented in the field more quickly (Varmus and Satcher 1997). The controversy resulted in multiple revisions of the Declaration of Helsinki and CIOMS guidelines on the use of placebos, yet consensus on this question has not been reached.

Finally, similar to clinical trials, population-based trials—particularly those conducted in resource-poor settings—increasingly must consider what, if anything, will be made available to study communities when the research is completed. Several national and international bodies have suggested that successful research interventions should be made reasonably available to host country communities (CIOMS 2002; National Bioethics Advisory Commission 2001)—or at least justify why such availability is impossible if that is the case (Nuffield Council of Bioethics 2002), while others argued that many donor or government commitments never could have been secured until study results were in hand. An alternative approach suggested that 'fair benefits' should be provided to communities, regardless of whether those benefits are directly related to the study intervention being tested (Conference on Ethical Aspects of Research in Developing Countries 2004). Recent HIV Prevention Trial Network (HPTN) ethics guidance acknowledges that although conclusive definitions of post-study access agreements may not be possible prior to testing the intervention, the development of a detailed, preliminary plan of post-study access is nonetheless necessary (HPTN 2009).

Important in the evolution of thinking about public health research ethics was a controversial legal case of 2001 related to a lead abatement trial conducted in the 1990s in Baltimore (*Ericka Grimes v. Kennedy Krieger Institute, Inc.* 2001). This trial targeted low-income housing units in old neighbourhoods that had significant lead paint in units and where units often were in disrepair; that is, where children would be at risk of lead poisoning due to the existing poor conditions (Farfel and Chisolm 1990, 1991, 1994; Pollak 2002). Despite evidence existing for decades documenting the danger of lead paint to children, no laws existed requiring that houses be safe or abated before they could be rented to families. In the trial, households were randomized to one of several different lead abatement strategies to see the effect on both household lead dust and

children's own blood lead levels of the different abatement strategies. Two families later brought lawsuits, charging that researchers failed to warn them in a timely manner that children might still be at risk of lead poisoning. This case was paradigmatic of certain types of public health research, in that it targeted a particular community, it dealt with prevention of a major public health problem, and, significantly, it was designed to respond to a series of baseline conditions that were harmful to public health. There remains no consensus regarding whether research is exploitive when situated in settings of neglect and when testing interventions that may improve conditions, but will not improve them as much as other, existing, but clearly unavailable interventions. Scholars have questioned whether conducting research on 'partial solutions' condones the idea that partial solutions are adequate for the disadvantaged (Farmer and Campos 2004; Spriggs 2004; Buchanan and Miller 2006; Kass 2008). Miller and Buchanan suggest that rejecting all research on partial solutions out of a 'presumption that a particular conception of justice will eventually prevail'—sacrifices the welfare of 'literally millions' of (in this case) children who could benefit from the results of the partial solutions tested through public health prevention research. Related, they assert that it is inappropriate to blame researchers for 'the lack of social consensus' on the right to better social conditions and that doing so is 'misplaced indignation' (Buchanan and Miller 2006). Others, however, suggest that even the perception of exploitation raised through this case is harmful for the research enterprise and suggests a need for 'true partnership in the research enterprise, particularly when proposed research involves vulnerable communities' (Mastroianni and Kahn 2002).

Ethical issues raised by genetic research

The rapid advancement of genetic research over the past two decades has presented new challenges for public health research, including issues of consent for storage of genetic material, return of genetic test results, and assignment of ownership of genetic material.

Because biospecimens used in genetic research are frequently collected and stored in a 'biobank' from which they are accessed for a wide range of future studies, it is not always possible to know how specimens may be

used in the future. Re-contacting participants each time their sample will be used has been viewed as impractical and overly burdensome to both researchers and participants, yet 'blanket consent', in which participants agree to any future use of their samples, has been criticized as an insufficient means of respecting participant autonomy (McGuire and Beskow 2010). While empirical work shows most participants support data-sharing initiatives that enable widespread use of their samples, participants expressed lingering concerns about the capacity of data-sharing initiatives to fully protect participant data, suggesting initiatives should be transparent to maintain trust with participant populations (Trinidad et al. 2010). At the same time, there is increasing opportunity for individuals to upload their own genetic data into private non-profit and commercial databases for use by a wide network of researchers, for example, through online initiatives such as 'Consent to Research' (http://weconsent.us/) and the 'Personal Genome Project' (www.personalgenomes.org). As biobanks have sprung up across the globe and information is increasingly available electronically, the potential for global data sharing is quickly becoming a reality (Kaye 2011). While such interconnectedness leverages the resources available to researchers and opens new opportunities for research, it amplifies the potential for uncontrolled use of specimens well beyond original and anticipated uses. Consent procedures for biobanking and the ethics of global data sharing is in its infancy, and ethicists are grappling with the challenges of developing controls and accountability mechanisms (Gottweiss and Lauss 2010; O'Doherty et al. 2011).

Disclosure of results from genetic tests performed during research also raises controversy. Some argue results should be returned as a way to respect autonomy and allow participants to find meaning in results even without clinical implications; returning results may also demonstrate reciprocity for having participated in research (Ravitsky and Wilfond 2006). Others counter that supplying genetic results that are often complex and offer limited clinical value would be misleading and potentially harmful (Beskow 2006). Even when results are readily interpretable and have clinical implications, informing participants of results requires retaining linkages to individual samples. The National Bioethics Advisory Commission and the National Cancer Institute's Best Practices for Biospecimen Resources state merely that the informed consent document contain a statement explaining whether, which, and to whom individual

results would be released (National Bioethics Advisory Commission 1999; National Cancer Institute 2011). Taking a stronger stance, the National Heart, Lung and Blood Institute convened working groups in 2004 and 2009 that drafted recommendations outlining conditions under which results ethically should be returned, circumstances in which research may but should not be expected to return results, and that emphasized the importance of community engagement when working with identifiable communities (Fabsitz et al. 2010).

Finally, genetic research has given rise to questions of identity, ownership, and property in ways not seen in other types of public health research. Lawsuits filed in the early 1990s and 2000s addressed ownership of biological material used in genetic research (*Moore v. Regents of the University of California* 1990; *Greenberg v. Miami Children's Hospital Research Institute* 2003; *Washington University v. Catalona* 2007) and plaintiffs claimed a property right to the materials developed from their genetic samples. Defendants argued that samples were 'donated' and individuals relinquished ownership rights when samples were collected. Case law to date has favoured the research enterprise in rulings that do not recognize participant ownership of biospecimens collected for research, yet questions remain, ethically, as to whether viewing biospecimens as property is appropriate. McGuire and Beskow outline numerous approaches to informed consent in genetic research, (McGuire and Beskow 2010), and the National Human Genome Research Institute maintains a comprehensive web resource for conducting informed consent in genetic research. In addition, new initiatives seek to address these challenges through participant engagement (Kaye et al. 2012). Finally, emerging participatory models propose the use of social media as a way to form relationships between participants and researchers. As a means of ongoing communication, these initiatives empower participants to make informed choices over the use of their samples and provide a mechanism to communicate findings as their interpretation changes over time.

Conclusion

Public health has been given significant attention in the bioethics literature only in the last three decades. Public health must balance furthering the

health of communities through education, surveillance, interventions, and regulations with needing to restrict the freedoms or privacy of individuals affected to the minimum degree possible while also addressing core commitments to social justice. Public health is granted statutory authority to protect the public's health and, indeed extraordinary public health improvement has been achieved through sanitary measures, restaurant inspections, immunizations, and health education. At the same time, it is expressly because of this authority that ethics has such a critical role to play. Clear frameworks of ethics that outline a need for data, minimizing of harms, fair procedures, and clear principles to follow, including transparency, reciprocity, and equity, can help public health fulfil its duty to improve health on behalf of all of us, while allowing individuals to feel confident that any restrictions are appropriate and fairly defined. Public health research requires some new considerations for research ethics including the need to be more cognizant of the implications of research for populations as a whole, for finding creative ways to seek community-wide input, and to begin to consider how to ensure that communities, as well as individuals, realize research benefit.

[1] Note that the 11th edition of the same textbook (1980) had a chapter entitled ‘Legal and Ethical Issues in Public Health’ by Sidney Shindell. The bulk of this chapter is devoted to legal issues in public health, however, rather than ethics issues, and thus is not discussed here.

[2] Note that this article describes the work of Edward Chadwick in England in the early 1800s demonstrating that differences in social conditions led to a more than twofold difference in life expectancy between upper and lower classes. Also in the 1800s, governments began conducting investigations of housing conditions and garbage heaps and mapping them in relation to outbreaks of disease, and by the end of the nineteenth century, state and local boards of health were being created to enforce sanitary regulations.

3.3

The right to health supports global public health

Carmel Williams, Alison Blaiklock, and Paul Hunt

Illustrations of human rights promoting and protecting health

We commence this chapter with a selection of very short illustrations of various ways in which human rights have been deployed to improve public health. We want to encourage readers to think of human rights as practical, useful, and effective in public health. Following these introductory illustrations we then explain human rights, and in particular the right to the enjoyment of the highest attainable standard of physical and mental health, and how they support public health.

Brazil Family Health Programme

Brazil enshrined the right to health in its Constitution in 1988 and subsequently framed their family health programme with the values and features associated with health rights. The legislative and policy reforms led to reduced health inequities, and improved health outcomes, shown in the reduction of maternal mortality (53.1% by year eight of the programme) and infant and child mortality (34% decline by year eight). Although the human rights-based approach was not comprehensive, has subsequently faced setbacks and remains a work in progress, the roll out of the new programme advanced the health of poorer women and children first (Bhalotra et al. 2016). This is consistent with a human rights-based approach to health (Bustreo et al. 2013).

Treatment Action Campaign in South Africa

The decision of the Constitutional Court of South Africa in *Minister for Health v. Treatment Action Campaign* held that the Constitution required the government 'to devise and implement a comprehensive and coordinated programme to realize progressively the right of pregnant women and their newborn children to have access to health services to combat mother-to-child transmission of HIV' (CCSA 2002, para. 135 (2) (a)). This decision led to the establishment of one of the biggest programmes in Africa to reduce mother-to-child transmission of HIV (Burton et al. 2015).

Empowering people to claim their health entitlements

My Health, My Voice is a human rights-based project in Uttar Pradesh, India, which used technology to monitor and display online data regarding illegal informal payments for maternal healthcare. A toll-free hotline was established through which women could report health providers' demands for these payments. Over a 15-month period, the hotline recorded 873 reports of informal payment demands. The project enhanced women's knowledge of their entitlements, as well as their confidence to claim their rights. Anecdotal evidence suggests that health providers' demands for informal payments were reduced in response to the project (Dasgupta et al. 2015).

The State Hospital, Scotland

In 2000, The State Hospital in Carstairs, Lanarkshire, Scotland, after a critical report by the Mental Welfare Commission in 2000, decided to use the Human Rights Act as a vehicle for change (Alliance 2013). Accordingly, the human rights of everyone—staff, patients, carers, and family members—were put at the heart of the hospital's services. A working group, led by senior management and involving clinical and non-clinical members of staff, was established. Consultative methodologies were devised for operationalising a human rights-based approach at the hospital. In 2009, an evaluation of the initiative found that the human rights-based approach had supported 'a cultural change … towards an organization with a more positive and constructive atmosphere with mutual respect between staff and patients' (Scottish Human Rights Commission 2009). This led to 'increased staff and patient engagement, increased work-

related satisfaction among staff and increased satisfaction among patients over their care and treatment' (p. 6). The new approach 'coincided with staff reporting a reduction in stress and anxiety' and patients 'noted significant and sustained improvements in their care and treatment and in the overall culture' at the hospital (Scottish Human Rights Commission 2009).

Ending child marriage

Current estimates are that although child marriage is declining, 12 million girls are married in childhood each year (Cappa 2018). Eliminating child marriage is a sustainable development goal (SDG) target and important to achieving other SDGs. Child marriage is a major violation of children's rights to health and education, to protection from abuse and exploitation, as well as other human rights. The numerous health impacts for children and their babies include complications of pregnancy and childbirth; physical, sexual, and psychological violence; and HIV/AIDS. Social movements to end child marriage and support married girls are growing. More than 900 civil society organizations from 95 countries, most of whom work in communities and many identify as youth-led, have formed the Girls Not Brides global partnership. The partnership's theory of change recognizes a range of community and collective approaches at all levels are necessary. These include empowering girls to know their rights; community leaders taking action to realize girls' rights; and national laws reflecting international and regional human rights standards (Girls Not Brides 2015, 2018).

Shaping Italy's health system

Italy's Constitution of 1948 protects the right to health: 'The Republic safeguards health as a fundamental right of the individual and as a collective interest'. The courts have decided a handful of important right-to-health cases, for example, on improving access to contraception. Crucially, this human right has explicitly shaped Italy's national health service, national health plans, and community health schemes, such as the initiative that delivers women's health information and services. The right has also explicitly shaped health interventions, including cancer screening

programmes. The guidelines for cancer screening remind health professionals that ‘access to screening is an application of a right’. A recent World Health Organization study on Italy concludes that applying human rights to women’s and children’s health policies, programmes, and other interventions has not only helped the Italian government comply with its binding national and international obligations but has also contributed to improving the health of women and children (Bustreo et al. 2013).

Introduction to human rights

These aforementioned examples illustrate different ways in which human rights have been used to improve public health: they guided policy reform so that people’s right to health entitlements were fulfilled; they used judicial action to redress power imbalances and rights violations that cost lives; they protected people who were powerless and marginalized by enabling them to challenge these power imbalances; and they underpinned social movements. In sum, human rights can be used to address human suffering, and to protect people from future harm arising from rights failings and abuses.

Our overarching aim in this chapter is to demonstrate to those working in global public health how the right to health, and other human rights, can make a meaningful contribution in their field of expertise. We build on the work of many others, including the authors of the corresponding chapter in preceding editions to this volume, hoping to extend the understanding that global public health, the right to health, and human rights are natural allies with common concerns and causes.

A recent survey of the literature on health and human rights, including the right to health, finds that ‘since the turn of the century, there has been a steady stream of academic books, articles, reports, and other publications on human rights and health, including the right to health’ (Hunt 2016). But it also demonstrates that the lens of the right to health has been directed more at healthcare than either public health or global public health. We endeavour to make an original interdisciplinary contribution towards redressing this imbalance.

In the following subsections, we introduce human rights and explain their modern history and status in law. We look at different ways in which human rights are used, and identify who has entitlements to rights, who carries

human rights obligations, and what a human rights-based approach to health means. We then, in ‘What is the right to health’, examine the meaning of the right to health, adapt and refine the right to health analytical framework, as set out in several publications (Hunt 2015) and in ‘Key features of the right to health’, identify key features of the right to health. This leads to ‘The right to health in practice’ where we look at how the right to health can be used in global public health with three case studies: climate change and children; Big Data and health; and international assistance and cooperation. In our conclusion, we return to the short illustrations at the start of the chapter, examined in the light of a human rights-based approach to public health.

What are human rights?

Human rights are grounded in respect for the dignity, well-being, and equality of every human being. They are a commitment to our shared humanity, are inspired by moral values, and the recognition that all of us are inherently entitled to rights simply because we are human. But human rights go further than moral claims; they are underpinned by international law, binding agreements that all of us—all people everywhere—are legally entitled to be treated with respect, dignity, and equality. This is a key human rights principle; others include participation and accountability.

Human rights guarantee the right of everyone to the enjoyment of the highest attainable standard of physical and mental health (hereafter abbreviated to the ‘right to health’ or ‘health rights’). They also require governments and others to take collective and organized actions that promote health and equity for everyone. Inequity is avoidable because it is the result of injustice and discrimination. Thus, human rights are key to public health achieving its aims of reducing mortality and morbidity and promoting health through the collective and organized actions of communities and societies (Winslow 1920; Acheson 1988). Similarly, human rights are essential for global public health achieving its aims of health and health equity for everyone worldwide through collective and organized actions that address transnational health issues and determinants.

In 1948 the Universal Declaration of Human Rights (UDHR) was adopted by the United Nations in response to the authoritarianism and its causes, and associated atrocities, of the Second World War. It begins: ‘All

human beings are born free and equal in dignity and rights' (UN 1948). The UDHR and subsequent treaties (often called covenants or conventions), such as the International Covenant on Economic, Social and Cultural Rights (ICESCR) (UN 1966b), and the Convention on the Rights of the Child (CRC) (UN 1989), turned these values into international laws which confer entitlements on people and impose obligations on governments, transnational corporations, organizations, and people whose roles and responsibilities affect others.

Although the underpinning of human rights by international law renders them powerful, their use is not limited to the courts, as we have shown in the given illustrations. Throughout the world, human rights play a crucial role in empowering people to claim their health and other entitlements, to challenge power imbalances, and to seek social justice. Accordingly, human rights can underpin transformative public health actions that address the health consequences of inequality and discrimination. Moreover, there is emerging evidence that human rights contribute to health gains for individuals and populations (Hunt et al. 2015).

Public health and human rights are natural allies

The disciplines of public health and human rights can complement, extend, and at times challenge each other. Just as public health programmes are essential to the realization of the right to health, so too can human rights help to reinforce existing and useful health programmes and policies and identify and shape new, equitable ones.

Public health workers and human rights advocates are motivated by similar concerns for the well-being of individuals and populations. They also want effective, integrated, responsive health systems that are accessible to all. Other similarities include the recognition of:

the importance of empowerment, laws, policies, evidence and analysis, advocacy, and collaboration to bring about change;
not only access to healthcare, but also to the social, environmental, and other determinants of health including water, sanitation, nutrition, health information, and education, and much more;
the need for collective efforts to improve well-being; health is not the sole responsibility of the health ministries and health systems, but belongs to a wide range of public and private actors and requires governments, the private sector, civil society, and communities to work together;
the underlying and structural causes of problems in society;
the important struggle against discrimination and disadvantage;
cultural respect;
social justice and challenging existing unfair distributions of money, power, and resources.

Human rights-based approaches to health shift public health well beyond biomedical paradigms and expand the focus on population morbidity and mortality to the dignity and well-being of everyone. Human rights challenges utilitarian, paternalistic, and neoliberal approaches to public health. Instead of prioritizing the ‘greatest good for the greatest number’, priority is given to those who are most disadvantaged and discriminated against (Rumbold et al. 2016). As a human right, health is seen as an entitlement, not something able to be bought, traded, or bestowed by privilege or altruism.

When viewed through a human rights lens, health issues are understood in terms of rights rather than problems requiring technocratic solutions. Public health workers become defenders of human rights who promote and protect human rights, and who enable people to claim and enjoy their rights. Their practice can include human rights frameworks and tools as we have illustrated, as well as public health methodologies, and their professional codes of ethics are underpinned by universally agreed moral values and international, regional, and national human rights laws. Public health services may have various forms of political and financial accountability; they also have binding obligations under international and national law which give rise to legal accountability for human rights.

Public health workers—and indeed everyone working to improve health—can use the right to health to help devise more equitable policies and

programmes; place important health issues higher up national and international agenda; secure better coordination across health-related sectors, as well as between services within the health sector; raise more funds from the treasury; build partnerships with civil society; analyse the activities of partner agencies, businesses, and international financial institutions; leverage more funds from high-income countries to low- and middle-income countries; use internationally accepted norms and standards (e.g. definitions of population groups); improve the terms and conditions of those working in the health and other sectors; and so on. The right to health is not just a rhetorical device, but also a tool that can save lives and reduce suffering, especially among those who are most disadvantaged. These goals all remain consistent with the most recent global development agenda, the SDGs, that aims to leave no one behind.

International human rights norms and laws provide a way to challenge growing threats to public health from global power and financial asymmetries associated with multinational corporations, trade and investment treaties, and environmental degradation. The UN human rights expert on a democratic and equitable international order, has called for assessments of the impact of trade and investment treaties on human rights, health, and the environment (de Zayas 2015).

The legality of human rights

Formal expressions and legal guarantees of human rights come from treaties, customary international law, national laws, and other sources of law that impose legal obligations on governments and others for the protection, respect, and fulfilment of human rights. These recognize a wide range of civil, political, economic, social, and cultural rights, including for example, the rights to life, participation in decision-making, to an adequate standard of living, education, a healthy environment (UN Human Rights Special Procedures 2018), and many others, some of which are referred to in this chapter. Human rights laws also recognize specific rights, including protection from discrimination, for some groups of people including women, children, those with disabilities, those experiencing racism, migrant workers, refugees and asylum seekers, and indigenous peoples.

The international community has agreed that all human rights are universal, inalienable, indivisible, interdependent, and interrelated (UN 1993). Being *universal* means that everyone is entitled to equally enjoy

their human rights without discrimination on any ground such as ‘race, colour, sex, language, religion, political or other opinion, national, ethnic or social origin, property, disability, birth or other status’ (CRC 1989). Actions to tackle inequality and discrimination are at the heart of human rights just as they are at the heart of public health. Recognition that all people should be treated with dignity underpins the compassion that is integral to the work of healing and the solidarity that is integral to the work of social justice.

Being *inalienable* means that no person can give or negotiate away their human rights or have their human rights taken away other than in very specific situations. There may be occasions where it is necessary to limit someone’s human rights for the sake of other people—such as when quarantine restrictions are needed to control an epidemic; we discuss next when this can be done legitimately.

Being *indivisible*, *interrelated*, and *interdependent*, means that all human rights must be respected, not just a selection. Respect for all human rights ensures respect for the dignity and worth of every person. In practical terms, the violation of one right can affect others—for example, when children are unable to enjoy their rights to food, water, and shelter, their rights to health, education, and protection may be seriously harmed.

Notably, very few human rights are absolute: sometimes *balances* have to be struck between rights, such as the right to privacy and freedom of information. Also, most human rights may be subjected to limitations, such as those ‘determined by law … and solely for the purpose of promoting the general welfare in a democratic society’ (United Nations, Article 5, 1966b). For example, an individual may claim she has the right to receive non-fluoridated drinking water in her home, but the community in which she lives may wish to receive fluoridated water on public health grounds. In this case a balance has to be struck between the individual’s human right (to private and family life) and a possible limitation (the general welfare). The Siracusa Principles are designed to ensure fair balances are struck by way of fair processes (see ‘Siracusa Principles’, to follow).

International human rights treaties, such as ICESCR and CRC, are legally binding on the states that ratify them. Ratification means states agree to be bound by international law to the treaty and they accept concrete legal duties to comply with the treaty’s requirements and prohibitions. States are then accountable for what they do and do not do to implement the treaty’s principles and provisions. International human rights declarations,

such as the UDHR, the Declaration on the Rights of Indigenous Peoples, and the Declaration on the Right to Development are non-binding, although many of them include norms and principles that reflect obligations that are binding under international customary and treaty law. Additionally, all states have national laws that protect some human rights.

Human rights-based approaches to health

A human rights-based approach to health 'requires adoption of an approach explicitly shaped by human rights principles' (Gruskin et al. 2010). It also means that health 'policies and programs will contribute to the fulfilment of human rights' (Gruskin et al. 2010) and indeed do not undermine people's enjoyment of their rights. The underpinning of human rights in international and national law brings real strength to human rights-based approaches to public health. Additionally, human rights principles, when operationalized in policy and programmes, empower people, and provide public health with the opportunity to promote equity, and improve health outcomes. We examine three different approaches to human rights in practice (policy, judicial, and empowerment); but we stress that in reality these all overlap and none is effective without the others.

Policy approach

Human rights principles should influence policymaking processes so that health policies and programmes promote and protect human rights including rights to equality and non-discrimination, participation, and to a well-functioning health system. This we call the 'policy' approach to implementing the right to health. A right-to-health perspective should be part of all local, national, and international policymaking processes that are relevant to people's health.

As with most public health endeavours, success in bringing about changes in policy requires close cooperation across a range of disciplines, and with the communities affected. Because of its role and expertise, public health has an indispensable contribution to make to the 'policy' approach.

Judicial approach

When human rights are not respected, protected, or fulfilled, another approach can involve the courts, tribunals, and other judicial and quasi-judicial processes (the 'judicial' approach). This approach has a vital role to play and throughout the world many courts have demonstrated that they have a crucial contribution to make. Court rulings have enabled people to gain access to medicines or other health rights entitlements in thousands of cases (UNHRC 2007; Gauri and Brinks 2008; Yamin and Gloppen 2011; Ferraz 2018).

Empowerment approach

The empowerment of people to know and claim their human rights entitlements is a third approach to the right to health, one which is also essential to both the policy and judicial approaches. When people know they have a right not to be discriminated against, to equal access to health services, to be treated with dignity, and that provision of essential services is a right, not an arbitrary act of charity, they can act, individually or as part of groups and movements. Such action can change social norms, practices, and the distribution of power, within and between communities and countries.

Human rights entitlements and obligations

Human rights law confers entitlements on all people and imposes obligations on governments (states), and others, who are called 'duty bearers' in human rights discourse. States that have ratified international and regional human rights treaties are accountable for compliance with their principles and provisions and mandated to report periodically to UN monitoring bodies. In 2013, the Optional Protocol to the ICESCR came into force. This made it possible for individuals or groups in states which had ratified ICESCR and the Optional Protocol, to submit a complaint to the Committee of the ICESCR in regard to state violations of their economic, social, and cultural rights, including the right to health.

Since 2008, a Human Rights Council accountability mechanism called the Universal Periodic Review has required all UN Member States to report on the actions they have taken to improve human rights in their countries, regardless of which treaties they have ratified.

The Special Rapporteur on the Right of Everyone to the Enjoyment of the Highest Attainable Standard of Physical and Mental Health is another accountability mechanism mandated by the Human Rights Council. The Special Rapporteur presents two types of reports to the Human Rights Council and the UN General Assembly (UNGA). The first are general thematic reports (for example, corruption and the right to health (UNGA 2017) or the SDGs and the right to health (UNGA 2016)); secondly, the Special Rapporteur undertakes visits to countries, following which a country report is written on the right to health, or specific elements of the right, with a view to holding the country to account for its right to health obligations. When rapporteurs encounter specific issues on which the existing jurisprudence gives little guidance, they offer their interpretations of the international right to health (Hunt 2016).

Civil society is encouraged to engage in all of these reporting processes, and provide shadow reports, as a means of keeping the processes transparent and meaningful.

Human rights obligations, including duties relating to the right to health, extend beyond states to members of society (UN 1948, preamble; UNCESCR 2000, para. 42). This includes health workers, families, communities, inter- and non-governmental organizations, civil society groups, and businesses including multinational and transnational companies, for example, pharmaceutical companies. One of the human rights responsibilities of states is to provide an environment in which the actions of all these individuals and groups is in accord with their human rights duties, and where people are able to claim their human rights entitlements.

When states enter into bilateral, multinational, or global agreements, including trade agreements, they are duty bound to ensure such agreements respect and protect human rights. The SDGs, adopted by all UN Member States in 2015, explicitly refer to human rights in their preamble, stating, ‘The 17 Sustainable Development Goals … seek to realize the human rights of all and to achieve gender equality and the empowerment of all women and girls’ (UNGA 2015). Furthermore, this global initiative uses as its catchphrase the mission to ‘leave no one behind’. This echoes the human rights imperative of equality and non-discrimination, and the public health commitment to reduce inequities.

Human rights are not without controversy

The right to health—like other economic, social, and cultural rights—does not escape controversy and ideological objections. Some states are reluctant to see it as a right of similar weight to others, such as the right to a fair trial. However, under international law, the right to health is an integral part of the international code of human rights, a right that is interdependent and indivisible from other rights and must be given equal treatment and attention (UN 1993, para. 5).

Despite the promise of human rights, they cannot by themselves resolve many of the complex problems pertaining to their realization. For example, despite human rights accountability mechanisms, there is little that most states can do to force other states to meet their human rights duties. Furthermore, in our globally interconnected world, where transnational companies control and own much of our health and general information, nation states remaining the primary human rights duty bearers has severe limitations. Nor do human rights present easy solutions to decisions to guide the prioritization of scarce health resources. However, the human rights principles of equality, non-discrimination, participation, and accountability are useful to guide responses to these challenges.

What is the right to health?

The right to health does not mean a right to be healthy (UNCECSR 2000, para 8). It is however, as recognized in international law, the right to facilities, goods, services, and conditions that are conducive to the realization of the highest attainable standard of physical and mental health. In some quarters, there has been a presumption that the right to health relates to personal health services. Such a narrow definition is in fact inconsistent with international human rights law, which encompasses clinical care, public health, and the determinants of health, such as access to water, sanitation, nutrition, housing, and education, as confirmed by Article 12 of ICESCR and Article 24 of CRC.

Under the right to health people have freedoms, such as the freedom from discrimination or non-consensual medical treatment and experimentation. They also have entitlements including to maternal, child, and reproductive health services; healthy workplaces and environments; the prevention,

treatment, and control of diseases, including access to essential medicines; and access to safe and potable water and sanitation.

The right to health is closely related to and dependent upon the realization of other fundamental human rights contained within international law. The rights to education, an adequate standard of living, life, privacy, and access to information, as well as other rights and freedoms, relate to and address integral components of the right to health.

International human rights law

The origins of the right to health in international law can be traced back to the 1946 World Health Organization's (WHO) Constitution which says: 'The enjoyment of the highest attainable standard of health is one of the fundamental rights of every human being without distinction of race, religion, political belief, economic or social condition' (WHO 1946). Two years later, article 25(1) of the Universal Declaration of Human Rights laid the foundations for the international legal framework for the right to health. Since then, the right to health has been codified in legally binding international and regional human rights treaties, and enshrined in many national laws, some of which are signalled in the following paragraphs.

The cornerstone protection of the right to health in international law is found in Article 12 of ICESCR. By 2018, 164 states had ratified this treaty, legally binding themselves to its implementation (OHCHR 2018).

Additional right to health protections are contained in international treaties that address issues specific to marginalized groups, or groups whose health is at risk from the effects of marginalization.[1] All countries have ratified at least one treaty with right to health provisions and with the exception of the United States, all countries have ratified the CRC (OHCHR 2018).

Authoritative and interpretive guiding principles of several of these treaty provisions on the right to health shed further light on the parameters and content of the right generally, and in relation to the application of the right to specific groups. Of special relevance are General Comment 14 on the right to the highest attainable standard of health adopted in 2000 by the UN treaty-body responsible for monitoring ICESCR (UNCESCR 2000); General Comment 15 on the right of the child to the enjoyment of the highest attainable standard of health adopted in 2013 by the UN treaty-body

responsible for monitoring the CRC (UN CRC 2013); international guidelines on HIV/AIDS and human rights (OHCHR and UNAIDS 2006); the Technical Guidance on the Application of a Human Rights-Based Approach to the Implementation of Policies and Programmes to Reduce Preventable Maternal Morbidity and Mortality (UN OHCHR 2012b); the Technical Guidance on the Application of a Human Rights-Based Approach to the Implementation of Policies and Programmes to Reduce and Eliminate Preventable Mortality and Morbidity of Children under 5 years of age, (UN HRC 2014); and *Ensuring Human Rights in the Provision of Contraceptive Information and Services: Guidance and Recommendations* (WHO 2014).

Far-reaching commitments relating to the right to health have been made in the outcome documents of numerous UN and WHO world conferences, such as the Alma-Ata Declaration (WHO 1978), the International Conference on Population and Development (UN 1994), the Fourth World Conference on Women (UN 1995), the Bangkok Charter for Health Promotion in a Globalized World (WHO 2005), the Rio Political Declaration on Social Determinants of Health (WHO 2011), the SDGs (UNGA 2015), and the Action Agenda from the Second Global Conference on Climate and Health (WHO 2016). These conferences and global commitments have helped to place international problems—including issues such as maternal mortality, mental health, non-communicable diseases (NCDs), health inequities, and poverty—on global agendas and their outcome documents influence international and national policymaking. Several refer to the right to health and/or health-related rights.

The UN Declaration on the Rights of Indigenous Peoples (DRIP) has particular importance. For indigenous peoples, colonization has often led to dispossession from their lands and territories; cultural subjugation; social, economic, and political marginalization; and consequential serious harm to their health. DRIP recognizes that for indigenous peoples, well-being is shared, holistic, and includes the relationship between people and environment, and is aligned with indigenous models for public health (see Chapter 10.6) (United Nations General Assembly 2007).

Siracusa Principles

Tragically, there have been situations such as the United States Public Health Service ‘Tuskegee Study of Untreated Syphilis in the Negro Male’

that began in 1932 and continued for 40 years (Centers for Disease Control and Prevention 2013) in which public health objectives have been used to justify what have been human rights violations, such as the withholding of information and treatment to develop an understanding of a disease. There are some occasions in which the public health measures necessary to respond to a serious threat to the health of a population or individual do require the limitation of other human rights. International human rights law sets out narrowly defined standards, called the Siracusa Principles (UN Commission on Human Rights 1984), as to when such limitations may be implemented legitimately. Such measures should only be taken when they are: necessary for the promotion of the general welfare; provided for in law and carried out according to the law; there is no other less intrusive and restrictive alternative; reasonable, based on evidence, and not discriminatory in any other way; subject to review; and of limited duration (UN ECOSOC 1985, Annex; UNCESCR 2000, paras. 28–9).

Regional human rights law

The right to health is recognized in human rights treaties adopted and monitored by regional human rights systems. These have effect only in their respective regions and include: the African Charter on Human and Peoples' Rights (Article 16); the African Charter on the Rights and Welfare of the Child (Article 14); the Additional Protocol to the American Convention on Human Rights in the Area of Economic, Social and Cultural Rights, known as the 'Protocol of San Salvador' (Article 10); and the European Social Charter (Article 11). Other regional instruments, such as the American Convention on Human Rights (OAS 1969) and the European Convention for the Protection of Human Rights and Fundamental Freedoms (Council of Europe 1950), also provide, through health-related rights and other provisions, protection of the right to health.

At the regional level there are also judicial and other mechanisms that adjudicate cases involving the right to health. A notable case in 2002 was the finding by the African Commission on Human and Peoples' Rights (ACHPR) of a violation of the right to health by the Federal Republic of Nigeria, on account of violations against the Ogoni people in relation to the activities of oil companies in the Niger Delta (ACHPR 2001). In 2009, the same tribunal held that Sudan had violated the right to health as a result of

exposing members of indigenous tribes in the Darfur region to serious health risks by destroying homes, livestock, farms, and poisoning wells. In so doing, the Commission recognized that the right to health extends to underlying determinants of health, including access to safe water, adequate and safe food, and housing (ACHPR, *Sudan Human Rights Organisation, et al. v. Sudan* Comm. No. 279/03-296/05 (2009).

Another important development has come from the Inter-American Commission on Human Rights (IACHR) which expressed its willingness to 'take into account' provisions of the regional treaty (the Protocol of San Salvador) related to the right to health when analysing the merits of a case, even though it lacked competence to determine violations under these provisions (IACHR 2000). In the case of *Gonzales Lluy et al. v. Ecuador*, **2015**, the American Court of Human Rights (IACtHR) recognized that the state has an obligation to supervise and monitor not only public hospitals but also private entities in the healthcare sector. The Ecuadorian government was found negligent in its supervisory duties for failing to properly test blood banks leading to a child becoming infected with HIV after a blood transfusion. It was found to have violated both the right to life and the right to humane treatment. Finally, in a recent case, *Poblete Vilches et al. vs. Chile*, the IACtHR ruled that 'the right to health is an autonomous right protected by Article 26 of the American Convention' and that the state was responsible for violations in relation to rights within article 26 (IACtHR 2018).

National laws

A study has shown that 55% of the constitutions of all nations have provisions regarding health rights (Heymann et al. 2013). In addition, 27 states have provisions regarding sexual and reproductive health and rights, and nine of these explicitly link the right to sexual and reproductive health to the rights to education, science, and/or to make autonomous decisions about sexuality and reproduction (Pizzarossa and Perehudoff 2017).

In some jurisdictions, these constitutional provisions have generated significant jurisprudence. The Constitutional Court of South Africa in *Minister for Health v. Treatment Action Campaign*, illustrated at the start of this chapter, is such an example. In many South American countries, with the right to health guaranteed in their constitutions, there has been 'an

‘explosion’ of litigation … (thousands of cases in Costa Rica, and hundreds of thousands in Colombia and Brazil) and a heightened disposition of judges to enforce the right to health through strong remedies in comparison to non-Latin American countries’ (Ferraz 2018).

These and numerous other laws and decisions at the international, regional, and national levels confirm that the courts have an important role to play in the protection, and fulfilment of the right to the highest attainable standard of health.

Key features of the right to health

In recent years, the Committee on Economic, Social and Cultural Rights, WHO, Special Rapporteurs on the right of everyone to the enjoyment of the highest attainable standard of physical and mental health, human rights experts, civil society organizations, academics, and many others, have developed ways of ‘unpacking’ or analysing the right to health with a view to making it easier to understand and apply to health-related policies, programmes, and projects in practice.

Accordingly, the following paragraphs set out 10 key features of the right to health. Some of the features overlap, for example, accessibility (in key feature nine) overlaps with non-discrimination (in key feature two). Also, some of the features have technical names, such as ‘obligations of immediate effect’, which reflect their legal provenance. Nonetheless, the features also reflect an emerging discourse for understanding some of the key characteristics of the right to health. ‘The right to health in practice’ applies these features, by way of illustration, in a more practical, operational way to the three case studies that follow on.

Laws, norms, and standards

As explained in greater detail, international, regional, and national laws, norms, and standards relevant to the particular issue, programme, or policy must be identified. These will include both general standards relating to the right to health, in addition to instruments that relate to specific groups and contexts (UNCHR 2003a, Annex 1).

Dignity, equality, and non-discrimination

Non-discrimination and equality are fundamental to all human rights, and to achieving the core human right entitlement of being treated with dignity. These entitlements are conferred from the first two articles of the Universal Declaration of Human Rights: ‘All persons are born free and equal in dignity and rights’ and ‘Everyone is entitled to all the rights and freedoms set forth in this Declaration, without distinction of any kind … ’ (UDHR, Arts 1, 2).

Participation

Participation is grounded in internationally recognized human rights, such as the rights to participate in the formulation and implementation of government policy (CEDAW, Article 7(b)), to take part in the conduct of public affairs (ICCPR, Article 25(a); UN 1966a), and to freedom of expression and association (ICCPR, Articles 19 and 22). All individuals and communities are entitled to active and informed participation on issues relating to their health, including policy making and accountability. Health professionals, and their associations, are also entitled to participate in decisions that will affect their employment and the work they do.

Accountability

Accountability lies at the heart of human rights where it has two main components: addressing past grievances and correcting systemic failure to prevent future harm (Tech Guidance HRC14/39, par 33.) Without accountability, human rights obligations can become empty promises. Accountability mechanisms provide individuals and groups (people with rights entitlements) with an opportunity to understand how states and others with human rights obligations (duty bearers) have discharged their obligations, and it also provides duty bearers with an opportunity to explain their actions. In this way, accountability mechanisms are transparent, and they help to identify policy or programme adjustments that are necessary to realize human rights entitlements. Accountability also tends to encourage the most effective use of limited resources, as well as a shared responsibility among all parties. Sometimes accountability is conflated with

monitoring but monitoring is only one step towards accountability. Accountability can be understood as monitoring, review (including independent review) in relation to human rights and other standards, and remedial action (Williams and Hunt 2017). Transparent, effective, and accessible accountability mechanisms are among the most crucial characteristics of human rights and they should extend to clinical care, public health, and the determinants of health.

International assistance and cooperation

In line with obligations envisaged in the UN Charter and some human rights treaties, such as the ICESCR (Article 2) and the CRC (Article 4), countries that need international support to meet their right to health obligations have a responsibility to seek cooperation and international assistance, and states that can provide such assistance have responsibilities to do so (Hunt et al. 2010; Maastricht Principles on Extraterritorial Obligations of States in the Area of Economic, Social and Cultural Rights 2011). Global inequality cannot be reduced without such support, as explained in the Alma-Ata Declaration, and this is also acknowledged in the SDGs (Agenda 2030, par 17.9). In times of emergency, people are entitled to disaster relief and humanitarian assistance, including public health services. States have a responsibility to cooperate in providing this support, as well as assistance to refugees and internally displaced persons (UNCESCR 2000, para. 40).

Respect, protect, fulfil all human rights

States have obligations to respect, protect, and fulfil all human rights, including the right to health, as explained and used by CESCR, the Committee on the Elimination of Discrimination Against Women (CEDAW), the Technical Guidance on the reduction of preventable maternal morbidity and mortality, among others (UN Human Rights Council 2012). These concepts are also enshrined in the Constitution of South Africa.

With regard to the right to health, the obligation to *respect* places a duty on states to refrain from interfering directly or indirectly with the enjoyment of the right to health. The obligation to *protect* means that states must

prevent third parties from interfering with the enjoyment of the right to health. The obligation to *fulfil* requires states to adopt the necessary measures, including legislative, administrative, and budgetary measures, to ensure the full realization of human rights, including the right to health.

This feature also draws attention to the indivisibility of human rights, and highlights the need to acknowledge the broad cross section of civil, political, social, economic, and cultural rights that underpin the wider determinants of health. Efforts to fulfil one right do not justify a failure to respect or protect other rights.

As we have explained, the right to health encompasses medical care and public health (see 'What is the right to health?' earlier) including the determinants of health. However, there is a tendency to give more attention to medical care and to neglect determinants. Because of that, in the application of this feature (see 'The right to health in practice', to follow) we give particular attention to determinants to ensure they are not neglected, marginalized, or overlooked.

Resource constraints and progressive realization

International human rights law recognizes that the realization of the right to health is subject to resource availability. Thus, what is required of a better resourced state today is of a higher standard than what is required of a poorer-resourced state. However, a state is obliged—whatever its resource constraints and level of economic development—to realize progressively the right to the highest attainable standard of health (UN 1966b, Art. 2(1)). In essence, this means that a state is required to be doing better in 2 years' time than it is doing today. In order to measure progress (or the lack of it) over time, indicators and benchmarks must be identified, and public health has a lot of experience in developing such tools. Progressive realization often involves making difficult decisions to ensure priority goes to those who are most disadvantaged. In human rights, it is not permissible for states to take steps that reverse human rights achievements. For example the present levels of service provision in healthcare may not be reduced, the current level of access to health services may not be lowered, and so on. If this situation, called retrogression, occurs, states must explain to UN monitoring committees why it has happened, as it is impermissible unless the state had no alternative actions available to it.

Obligations of immediate effect

Despite resource constraints and progressive realization, the right to health also gives rise to some obligations of immediate effect, such as the duty to avoid discrimination (UNCESCR 2000, para. 43). These are obligations without which the right would be deprived of its *raison d'être* and as such they are not subject to progressive realization, even in the presence of resource constraints (UNCESCR 1990, para. 10). Guidelines adopted by the UN monitoring committees are helping to clarify what these might be and have highlighted: agreement of a national plan of action relating to health, including sexual and reproductive health; provision of essential drugs as identified by WHO; provision of reproductive, maternal, and child healthcare; immunization against major infectious diseases; prevention, treatment and control of epidemic and endemic diseases; and training of health personnel. Clarification of minimum core obligations remains an ongoing and important debate.

Available, accessible, acceptable, and good quality

All health services, goods, and facilities should comply with each of these four requirements. For example, all essential immunizations should be *available* within the country. Additionally, they should be *accessible*. Accessibility has four dimensions: accessible without discrimination, physically accessible, economically accessible (i.e. affordable), and accessible health-related information. As well as being available and accessible, immunization campaigns should be provided in a culturally *acceptable* manner. This requires, for example, planning and coordination with community leaders. The *good quality* element will require, for example, ensuring the integrity of vaccine cold chains.

Note the similarity between these requirements and the four 'As' of public healthcare envisaged since the 1978 Alma-Ata Declaration: geographical accessibility, financial accessibility, cultural accessibility, and functional accessibility (WHO 1978b).

Strengthening health systems

At the heart of the right to the highest attainable standard of health lies an effective and integrated health system, encompassing healthcare and the underlying determinants of health, responsive to national and local priorities, and accessible to all (UN HRC 2008). The right to health cannot be fulfilled without a well-functioning health system (Backman et al. 2008). In essence, this means that the six components of a health system as identified by WHO—service delivery, health workforce, information, medical products, vaccines, and technologies, financing, and leadership and governance—are available, accessible, acceptable, and of quality to all, without discrimination. However, a health system is more than simply these six components. It also includes the people for whom it exists and a human rights perspective of a health system keeps these people at its centre. As Alicia Ely Yamin has written, 'If health systems are understood as core social institutions, it follows that the choices to be made cannot be seen just as technical choices but rather as reflecting and embedding values and norms of the larger society, including in relation to equality, dignity, and human rights' (Yamin 2016, p. 104).

The right to health in practice

The key features of the right to health underscore what the right to health contributes to public health. The preoccupation with dignity, equality, and non-discrimination requires a state to take effective measures to address the health inequities that characterize some populations. The focus on active and informed participation requires a state to adopt, so far as possible, a 'bottom–up' participatory approach in health-related sectors. The requirement of accountability can help to ensure that health policies, programmes, and practices are observant of human rights, and offer remedy when necessary.

Crucially, the key features of a right-to-health framework are not merely to be followed because they accord with sound management, ethics, social justice, or humanitarianism. States are required to conform to the key features *as a matter of binding law*. Moreover, they are to be held to account for the discharge of their right-to-health responsibilities arising from these legal obligations.

Having looked at the legality of human rights, the meaning of the right to health, and having identified its key features, we now turn our attention to what this means in practice. We apply this approach to critically important global public health issues—the impact of climate change on children's right to health, the digitization of health through Big Data, and overseas development assistance.

Case Study 3.3.1 The Impact of Climate Change on Children's Right to Health

Climate change is an enormous threat to global health (see Chapter 2.9). The greatest burden of climate change is borne by low resource countries and especially by poor children (Smith 2014). Children are especially vulnerable because of their growth and development, unique physiology and metabolism, reliance on adults and families, and the conditions in which they live, learn, work, and play. Consequently their health is at greater risk from climate-related events, infections, and pollutants, with the youngest and most disadvantaged children being most vulnerable (Ahdoot et al. 2015).

Climate change impacts on children's right to health and indeed all their human rights–their rights to life, survival, development, health, food, water, sanitation, a healthy environment, family, education, housing, safety, protection, participation, culture, heritage, and so forth (Knox 2016; United Nations General Assembly 2017). Without effective mitigation and adaptation strategies, climate change has life-long consequences for today's children and brings increasing harm to future generations of children. However, well-designed climate-related actions bring opportunities to improve the health and well-being of children and future generations (Hosking et al. 2011).

Laws, norms, and standards

Human rights laws, norms, and standards are used to reduce the harm that climate change causes on the well-being of children. Under the United Nations CRC, children are entitled to special protection measures and assistance to ensure their survival and development and that they are treated as human beings equal in dignity and worth with adults. Their evolving capacities as they grow and develop require different priorities and approaches at different stages of development throughout their childhood to ensure their right to health. Children's best interests should be central in considering all decisions that may affect their health and development (United Nations Committee on the Rights of the Child 2013). There are obligations in international law for actions that protect the rights and best interests of children, including their right to health, from the impact of climate change (United Nations General Assembly 2017).

The Paris Agreement on climate change recognizes the rights of children and people in vulnerable situations, intergenerational equity, and the right to health in its preamble (Conference of the Parties 2015). In its General Comment on the rights of the child to health, the UN Committee for the Rights of the Child included their right to a healthy environment and said climate change 'is one of the biggest threats to children's health and exacerbates health disparities. States should, therefore, put children's health concerns at the centre of their climate change adaptation and mitigation strategies (para. 50)' (United Nations Committee on the Rights of the Child 2013). The

UN Committee regularly makes recommendations about climate action in its in reviews of states' progress.

Dignity, equality, and non-discrimination

The burden of climate change is spread inequitably within and between countries. Those who have done the least to cause climate change are the worst affected and yet have the least economic and infrastructure resources for adaptation. Mothers and children, especially girls, are particularly affected (Metcalfe 2015). Climate change aggravates existing inequities, even leading to violent conflict over reduced resources and forced migration (Watts et al. 2015) and compounding other discrimination and injustices experienced by children.

If all children are to equally enjoy their right to health free of discrimination, climate-related actions must prioritize those children who are most disadvantaged, so that they are among the first to benefit. In practice this may require changing current priorities and ensuring more resources for these children, especially those experiencing multiple discrimination and living in vulnerable situations.

Participation

It is only recently that international climate negotiations have considered the rights of children and children have had some—albeit limited—opportunities to be heard. Children, especially those most affected, have the human right to participate and contribute to decision-making about matters which affect them and their health in accordance with their age and maturity. This requires having safe, child-friendly, and age-appropriate processes to support children to have their views heard and taken seriously. It may include them participating in legal and policy processes about health and the environment; priority-setting; the development and delivery of mitigation and adaptation policies and programmes; and accountability mechanisms. Participation has practical benefits: if children are involved in the development, delivery, and evaluations of programmes, the programmes are more likely to be effective (Children in a Changing Climate 2015).

Public health services should support children and their families' participation, including in the design, development, and evaluation of programmes. For example, although in times of extreme weather events and other disasters children carry out family and community duties, it is uncommon for them to be involved in disaster risk reduction planning. Yet their practical and creative ideas and unique knowledge of local environments mean they can make important contributions (Mudavanhu et al. 2015).

Many children are active environmental advocates. In several countries children are taking legal action, arguing that the state's obligations to hold some resources in common for all people, includes an obligation to protect the earth's atmosphere for children now and in the future. For example, Rabab Ali, a 7-year-old girl in Kawachi, petitioned Pakistan's Supreme Court about plans to develop a coal field, saying that atmospheric pollution harms and threatens the rights of Pakistani children and future generations, including their right to mental and physical health (Sabin Center for Climate Change Law 2016).

Accountability

There are some opportunities to hold states accountable at an international level for the impact of their climate-related actions on children through mechanisms under the Paris Agreement and the SDGs. These are weak mechanisms, especially for the magnitude of the task. The human rights mechanisms of the UN Human Rights Council, human rights treaty monitoring bodies and special procedures are also weak but can supplement the others. As countries develop and strengthen

national mechanisms for accountability there will be increasing opportunities to hold people, businesses, and other organizations accountable for the impact of actions on children.

Accountability mechanisms at international, regional, national, and local levels should include opportunities for the participation of children and child-friendly processes, and for consideration of the right to health of future generations of children. Unless data are disaggregated by age, sex, and other characteristics, it is not possible to hold states accountable in relation to their health rights obligations for *all* children.

Accountability requires consideration of the differentiated responsibilities for climate change and remedial action. High-income countries have benefited economically from their high greenhouse gas emissions. It is plainly unfair that the health of poor children throughout the world suffers the consequences. Countries with the highest emissions for their population must rapidly reduce their own emissions as part of remedying past, present, and future injustices against children. They also have urgent human rights duties to provide remedial action (including finance) for losses and damage suffered already by climate vulnerable countries and support their adaptation efforts (Hunt and Khosla 2009; Office of the UN High Commissioner for Human Rights 2015).

International assistance and cooperation

Unprecedented international cooperation is needed to reach the Paris Agreement's aspirational goal of limiting global warming below 1.5° and avoid catastrophic damage to global health. The human rights responsibilities of states include actively supporting—and not obstructing—the realization of the right to health for people in other countries. This requires working for an equitable international order and healthy environmental conditions for all including measures that will stop and reverse climate change (Hunt and Khosla 2009).

Human rights require states to act to the 'maximum extent of available resources'. High-income countries have a human rights obligation to share resources with less resourced countries so they have the resources they need to address climate change. Considerable increases in international assistance are needed to build climate-resilient health services and programmes. Health adaptation has however been largely overlooked in international assistance: between 2003 and 2017 less than 1% of the development funds available for adaptation through global climate change financing mechanisms, was for health sector adaptation (Watts et al. 2018). International assistance for health adaptation should pay special attention to poor children in low-income countries because they bear the greatest health impact of climate change.

Respect, protect, and fulfil all human rights

Tackling the impact of climate change on children's right to health requires action on determinants to respect, protect, and fulfil all of children's human rights. For example, for indigenous peoples, including children, climate change may mean displacement from their traditional lands and resources; disruption of their heritage, family life, cultural identity, and knowledge, and spiritual relationship with the natural environment; increasing poverty and marginalization; and direct and indirect harm to their health (Jones et al. 2014). Climate-related actions have potential to support or harm the well-being of indigenous peoples: for example, forced displacement of indigenous peoples from their traditional lands to build hydroelectric dams has caused serious human rights violations (Tauli-Corpuz 2017). When a state respects the right of indigenous peoples to guardianship of their forests; ensures the right is protected from interference by others (for example, multinational logging companies), and takes the legal, administrative, and budgetary measures necessary to fulfil the right, then this also respects traditional health practices and other health-related rights—as well as benefiting global climate mitigation.

Mitigation and adaptation plans made by states, regional, and intergovernmental organizations should address the human rights impacts of climate change, with a strong focus on respecting,

protecting, and fulfilling the rights of children and other vulnerable groups. Plans should include progressive improvements for child health services and programmes and the underlying determinants of health (Williams 2015). Climate-related actions should not cause retrogression of human rights: for example, the intention of increasing biofuel crop production may be to reduce use of fossil fuels but if done by displacing poor farmers from their land, may cause serious human rights violations, including of children's rights to health, food, education, a family environment, an adequate standard of living, safety, and so forth.

Available, accessible, acceptable, and good quality

There is considerable potential for public health co-benefits from climate-related actions (Watts et al. 2015). Climate-related public health services and programmes should be *available* to children, especially children living in climate vulnerable countries and situations. They should be *accessible*. This means prioritizing those children experiencing the greatest disadvantage; ensuring that access is not affected by physical barriers from location, distance and so forth, or economic cost; and enabling children to easily access information about health and climate change (for example, in the school curriculum). They should be provided in ways that are appropriate for the age and culture of the children served, i.e. *acceptable*. They should be informed by evidence, of sound *quality*, and provided in ways that support the best interests of children. In doing this, services should recognize the diverse needs of children—for example, protocols should include availability, accessibility, acceptability, quality criteria (AAAQ) for children who live with disabilities or whose caregivers do, and child-headed families.

Strengthening health systems

Health services can contribute to mitigation through reducing their own greenhouse gas emissions. This can include ways that come with co-benefits for the children: for example, when clinics are held in communities, travel-related emissions are reduced and physical accessibility and affordability can increase; and when hospitals stop using coal as a source of power, children are less exposed to harm from air pollution.

Health systems face considerable challenges in adaptation to climate change. Climate resilience has to be operationalized into each of WHO's six building blocks of health systems (World Health Organization 2015). The basic public health actions that are the most effective immediate general adaptation measures—such as vaccination, essential child health services, clean water, and sanitation, increasing disaster risk management capacity, and reducing poverty (Smith 2014) are all key to improving child health.

Case Study 3.3.2 An Impact Assessment of Big Data Using the Right to Health

Big Data is beginning to radically transform healthcare in multiple ways—through its use in electronic health records, data sharing, diagnostic tools, and treatment. These new technologies are changing the health and public health landscapes. Examples of the roles of digitization in healthcare include personalized medicine (a patient's treatment can be specifically tailored to their genetic, genomic, social and environmental profile) (Parry and Greenhough 2018), DNA sequencing (where the resulting vast amount of data is stored in bio banks), forensic, genetic or medical databases, including all the data from public health studies and clinical trials—and all of which can be re-

purposed for various technical inventions. These large data sets are driving the burgeoning artificial intelligence (AI) industry in healthcare. Where available and accessible these technologies offer improved public health, clinical care, and patient management; where they are not, inequities in health will likely result.

Blockchain technology also plays a role in health, with the technology, previously more associated with crypto currencies, being used to keep large health data sets more secure when data is shared. A focus on data security, although crucially important, must not become a distraction from other right to health threats posed by Big Data. In particular these threats may arise from data ownership and how equitably data will be used in the future.

Here we examine Big Data through a right to health lens and identify opportunities and threats to health equity and to the right to health in a new data-driven economy. We suggest that just as governments have been expected to carry out human rights impact assessments prior to adopting and implementing policies (MacNaughton and Hunt 2009; MacNaughton and Hunt 2011), so they should before embarking on the use of Big Data in health and other domains.

Laws, norms, and standards

While some health data sets are collected and controlled nationally, particularly people's medical records, much of the data feeding into global databases is derived from individuals contributing their own data to organizations beyond the borders of their resident state. This includes fitness and lifestyle data derived from wearable devices, or personal information uploaded into Facebook and other social media, as well as far more clinical and medically detailed data such as DNA sequencing, or clinical trials information. The rules, regulations, and laws governing how data can be used, and how individuals providing the data are protected, are not universal, although there are some regional regulations, for example, the European Union's General Data Protection Regulation (GDPR) https://www.eugdpr.org/. Collection and use of data for Big Data sets may be overseen by professional ethics, developed to guide fair use of data, but such codes of ethics are not legally binding.

National laws need to ensure that personal data is collected, stored, and used in ways that respect, protect, and fulfil human rights entitlements; but how can this be achieved beyond national borders? International human rights law provides such a facility. All use of Big Data, however the data sets were developed, even if ethically or with individual consent, must not subsequently be used in ways that violate human rights, including the right to health. For example, this means that, as a matter of law, Big Data must not be used, either when gathered or at a later time, to discriminate against people in terms of their right to health, including their participation in the health system, or to increase health inequities.

Dignity, equality, and non-discrimination

There are vast global inequalities in relation to data: from the personal (being literate, owning mobile phones, having internet access), to national information systems (functional national statistical offices, electronic information systems, electronic health information systems, a Big Data-driven sector that uses and develops electronic applications). Those countries, usually low-income countries, without sophisticated and extensive electronic infrastructure will be left further behind from the benefits of data-driven health gains, resulting in increased global health inequality, unless there is specific international assistance and technical support provided from high-income countries to address information systems deficits. There are great risks that, for example, wealthy people in high-income countries will have access to personalized medicine, tailored to their own genomes, while millions in poor countries continue to die prematurely from neglected tropical diseases, and other conditions of poverty. This is an example of gross inequity in public health, and a human rights failing at an international level, which requires urgent remedy.

Big Data enthusiasts cite its usefulness in many health domains, aside from clinical purposes. These uses include social media's role in monitoring and tracking epidemics and monitoring SDGs (Harvard Humanitarian Initiative, MIT Media Lab, and Overseas Development Institute 2016). Because of the human rights imperatives that inequality must not increase and there is no discrimination in the delivery of healthcare, it is vitally important to disaggregate data collected by not just looking at the data to determine the characteristics of those who contributed to the data sets, but also to understand who has not. When considering the use of Big Data to track epidemics, for example, there are still large pockets in the world where communities live without internet access (Williams and Hunt 2017). The percentage of the global population with access to the internet at the end of 2017, was 54.4%, ranging from 95% in North America to 35.2% in Africa (Internet World Stats 2018). Even these statistics require far greater disaggregation: for example, several African nations have less than 10% internet coverage, with Eritrea the lowest on 1.4%. If there is a global shift to monitoring epidemics through social media, widely considered more efficient and accurate than traditional health surveillance, those communities or countries living beyond internet penetration are at risk of invisibility during health or humanitarian crises.

As discussed earlier in 'Key features of the right to health', there are national and international human rights obligations to address these inequalities and discriminations, including through international assistance and cooperation (see 'Dignity, equality, and non-discrimination' and 'International assistance and cooperation')

Participation

The human right to participation means people are entitled to be part of decision-making processes that affect their lives and their health, and also to decision-making processes about health policy. At the least, when it comes to the use of their own data, people have the right to decide whether or not their data can be used for any purposes beyond the stated reason for its collection. Ownership and terms of use of the data must be clear and obvious, so that contributors to data sets are not later surprised to find their provision of personal information has been used to discriminate against them. This could, for example, occur if details of a person's dietary or other lifestyle factors, gleaned from social networks or sporting achievements applications, are shared with agencies that could withhold services on the basis of this information, or charge varying rates for the service on the basis of this information which was not provided directly to the service provider. Health insurance premiums could be an example of this.

Accountability

Over the past few years, use of Big Data has been plagued with scandals: for example, in the United Kingdom in 2016 over one million confidential patient files were given freely, and without hiding personal identities, to a Google-owned company to develop privately owned apps for clinical use; throughout 2016–2018 details were released about the extent of data mining through Facebook networks to influence voters and US and Brexit election results. As mentioned already, rules have now been introduced to control aspects of data collection, to protect privacy. However, such rules focus more on rights to privacy than they do on the longer-term consequences, for example, on who will own this data in its re-purposed presentations in the future. It is difficult to predict how data collected now will be used in the future, but our social and economic transactions, and healthcare, are now completely dependent on data. In order to protect social rights, such as the right to health, use of Big Data must be transparent, and there must be accountability for the human rights implications of how this data is subsequently used. Data processors need to be held to account for the human rights implications of the products they develop: for example, will data be gathered in discriminatory ways (perhaps from poorer communities and countries who use public health services), but will the resulting products be used only by individuals or their insurers who can afford

to pay for them? As discussed earlier, human rights require that duty bearers are held accountable by way of a process which includes monitoring, review against human rights and other standards, and remedial action (see ‘Key features of the right to health’).

Respect, protect, and fulfil all human rights

Big Data arises from multiple data sets in social, economic, and political domains. It is imperative that people’s rights in each of these domains are respected and protected during the collection and use of data, and that the integrated data are not used to discriminate against anyone in each of the domains. For example, domains of data about ethnicity, poverty, and crime might be combined in order to locate emergency health services where they are most needed which would be advancing equitable access to healthcare. However, the data could also result in biased algorithms that lead to disproportionate policing in areas where a minority population resides, leading in turn to increased arrests in that area. This could be discriminatory, and a violation of people’s rights to privacy and to justice.

Available, accessible, acceptable, and good quality

The benefits of Big Data should be available, accessible, and acceptable and based on good quality information and methodologies. When a state has determined, in a participatory way, the health services and facilities that can be provided from its maximum available resources, it is then obligated to ensure these are of good quality and available, accessible (including financially accessible), and acceptable to all. This covers such issues as ensuring that the datasets from which applications develop are built from quality, robust data, with privacy protected. Is the use of the data agreed to and acceptable to the people from whom the data was collected? Health services that arise from the use of Big Data, for example health apps to assist with diagnosis of diseases, or personalized medicine based on a person’s genome, must meet the ‘available and accessible’ criteria and avoid increasing inequities. For example, if patient information and notifications switch to digital systems, does this discriminate against people without smart phones, and result in them losing access to these services?

Strengthening health systems

The health system is the core institution through which the right to health can be fulfilled. Data is an essential component of health systems, used for improving patient management, providing health information, and importantly, to monitor the health system’s performance. As data sets increase in size, and as multiple data sets are integrated, it is essential to monitor and review that this use of Big Data continues to strengthen the health system. Right to health impact assessments should be undertaken before installing or implementing data-driven new technologies. Assessments are needed to question whether such technologies are protecting and respecting people’s rights; they can guide their use so technology strengthens, not weakens, health systems and thereby can fulfil people’s health rights entitlements. Questions about Big Data-driven technologies and their impacts on health systems would cover both technical infrastructure aspects, such as the robustness of the new systems and their vulnerability to hackers or power outages, through to ownership of the systems and the data contained within them.

Case Study 3.3.3 International Assistance and Cooperation and the Right to Health

One element of the right to health pertains to the obligation on states to provide international assistance and cooperation. It is incumbent upon states that can afford to do so, to offer assistance and cooperation to states who request it in order to meet their human rights obligations. States have an obligation to seek such assistance when they do not have available resources to meet their right to health duties. There are also global aid agreements arising from the Alma-Ata Declaration, the SDGs, and a commitment made by OECD countries in 1970 to spend 0.7% of gross national product (GNP) on aid (OECD, n.d.). Most OECD countries have not yet achieved that level of expenditure on aid, although global health spending has increased dramatically since 2000. WHO estimated $19 billion was spent on development assistance for health (DAH) in 2015. After a decade of rapid growth from 2000 to 2010 (up 11.4% annually), DAH grew at only 1.8% annually between 2010 and 2016. In low-income countries, DAH made up 34.6% of total health spending in 2016 (IHME 2016; WHO 2017). This is partially in response to the attention brought to global health and other inequalities from the Millennium Development Goals (MDGs), and SDGs, but also because of funding from global health initiatives such as The Global Fund to Fight AIDS, TB and Malaria, Global Alliance for Vaccines and Immunization (GAVI) and the Gates Foundation. Non-government organization (NGO) funding made up 30.1% of total DAH disbursed in 2016, whereas in 1990 it contributed only 7.6% of total DAH funding. NGOs collectively disbursed more funds than any other group by a wide margin (IHME 2016, pp. 32–3). Usually NGO funding is directed to the health initiatives pertinent to their own missions. The capacity of such organizations, and the non-state sector as a whole, to have an impact of people's right to health entitlements is therefore considerable.

In addition to the international human rights obligation to seek and provide international assistance and cooperation, when such assistance and cooperation is provided its delivery must conform to the requirements of human rights law. In this case study, we use the right to health framework to explore issues that global partners must consider when shaping aid interventions, so they comply with duties to respect, protect, and fulfil health rights.

Laws, norms, and standards

Development assistance must be compliant with international human rights law, as well as national laws and regulations. In the former, this pertains to such considerations as delivering assistance without discrimination (see next section), and at the national level, it will mean ensuring that, inter alia, health personnel will not be trained to deliver services beyond their regulatory scope. An example might be not training nurses to provide minor surgery if they are not permitted to perform such procedures.

A human rights-based approach to health recognizes that health is a right, and people have human rights entitlements to health services. International providers of assistance for health services are therefore assisting the fulfilment of people's rights, and empowering people to recognize and claim these rights entitlements. This is a different conceptualization of aid initiatives from ones of charity or philanthropy where beneficiaries may be viewed as fortunate to receive services but are not considered to have equal rights to them.

Dignity, equality, and non-discrimination

Assistance must not be provided in a discriminatory way, even when national law results in such discrimination. Examples of discrimination in health can be found when only married women can

receive some health services, or husbands' permission is required for services, or services are prioritized for people working in the formal sector, and so on.

International actors must therefore examine issues of inequality and discrimination in the countries they work to identify where interventions are most needed to reduce health inequities in that country. Treating all people with dignity is a fundamental value on which all human rights are based, and in aid programmes, that extends to the way in which people are presented in fundraising activities in donor countries.

Participation

When providing assistance and cooperation, international agencies need to ensure there is participation at many levels: that the state welcomes and invites their support, that local partners are leaders in the design and implementation of support, and the people for whom services will be provided have contributed meaningfully to all aspects of the initiative and its delivery.

Accountability

Human rights require effective accountability arrangements to be put in place for the human rights obligations arising from international assistance and cooperation. Accountability in aid initiatives is frequently limited to financial accountability, but human rights accountability is much more than this. People have human rights entitlements to know how decisions are made about the health system and provision of services. This includes for international assistance, at the least, transparency around: approval processes for international assistance support; the nature of services, products, or funds being delivered; location of services; how the quality of health services will be monitored; and whether services are provided in a non-discriminatory and equitable way. Human rights accountability necessitates the use of transparent processes to check that aid initiatives respect, protect, and fulfil human rights, remembering that rights are indivisible—so it is not acceptable to promote one health service at the expense of other health or other services, unless this is an agreed approach to the national plan. (For example, a country as a whole may decide to forego some tertiary level care to ensure primary healthcare reaches everyone). This is explained in 'Strengthening health systems'.

Respect, protect, and fulfil all human rights

Health aid cannot be sustainable without considering the broad determinants of health and their related rights. For example, assistance to improve a healthcare service such as child health is of limited use if children live in communities that do not have potable water, sanitation systems, or schools. Similarly, health aid programmes to educate midwives are unlikely to succeed in the long term if midwives are not paid adequately or if they are subject to violence at home or at work. It is therefore important that determinants and related human rights are assessed as part of international assistance and cooperation, and ways of addressing these rights are identified.

Available, accessible, acceptable, and good quality

International assistance and cooperation for health must be delivered or directed so that their support for health services meet the AAAQ criteria.

- Under availability, questions should be asked about what is required to make a health service fully available. This is not just about where the service is to be provided, but, for example, what medicines and other supplies are needed, and how will they be made available in a sustainable way. Similarly, how will staff be trained and employed so they are available for these services?
- Under accessibility, aid initiatives might consider who can access the service in terms of gender, disability, place of dwelling, or knowledge of such services. Care must be taken that groups, for example, indigenous people, are made aware of services and are helped to access them.
- Acceptability calls for culturally appropriate care to be made available. For example, are new services planned to be delivered in a way that is acceptable to women in minority or indigenous communities? Will health workers speak the languages spoken by disadvantaged groups?
- Quality healthcare is critically important and lower standards are not acceptable simply because recipient countries have fewer economic resources. This means that health workers must be well trained and supported, medicines must be within use-by dates, and countries that receive assistance should not be treated as dumping grounds for obsolete second hand equipment that will not be serviced, or as a means of claiming tax rebates on the 'value' of the goods donated.

Donors of health aid should include a right to health impact assessment of their initiatives before implementation, to consider the possible impact of a new or expanded service on the AAAQ of other health services. For example, well-funded stand-alone interventions for some health services may draw health professionals and other resources to them, weakening other core services—thereby resulting in a reduction in availability and quality (Williams and Brian 2013). At all times, donors must consider the sustainability of any interventions, in order to avoid commencement of services that will not endure, thereby later contributing to a regression in health rights fulfilment.

Strengthening health systems

Because the health system is the key institution through which the right to health can be realized, international assistance must take care to work in ways that promotes the long-term sustainability of the system. Initiatives must work in keeping with the national health plan. They should also strengthen the health system's capacity to provide quality health services for all, addressing inequities so that the most disempowered and worst off have their rights fulfilled first. Health impact assessments should be undertaken before implementing aid initiatives to systematically check the health system will be strengthened, not weakened, by international assistance.

Conclusion

We began this chapter with illustrations of successful right to health initiatives from around the world in high-, middle- and low-income countries, and concluded with detailed case studies demonstrating the right to health in practice. Together, these are examples of human rights supporting global public health.

The right to health entitles all people to a package of health services, facilities, and goods, extending to healthcare, and public health, including the underlying determinants of health, such as access to safe water, adequate sanitation, and health-related information. This package must be available, accessible, and of good quality. Also, it must be sensitive to different cultures, thus, acceptable. Health systems are the key institution through which healthcare and public health are delivered. They must be sites of inclusion, where people can participate in policy making and planning. In this way, health systems will have many features that are common to all countries, but there will also be differences between countries that will reflect their different disease burdens, determinants of health, cultural contexts, resource availability, and people's priorities.

Whichever approach and combination of approaches is employed, the objective is to respect, protect, and fulfil people's right to health.

Key points

The right to the highest attainable standard of health is enshrined in several international treaties and numerous national constitutions.

International law recognizes that all people have human rights entitlements and states have binding obligations to uphold these rights.

Public health and the right to the highest attainable standard of health are natural allies both seeking effective, integrated, responsive health systems that are accessible to all.

The key features of the right to health assist in understanding and responding effectively to public health issues and reducing global and national inequities.

The right to the highest attainable standard of health can be understood as a right of everyone to public health and health services and the underlying determinants of health.

ACKNOWLEDGEMENTS

In a number of ways, this chapter builds on the corresponding chapter, 'The right to the highest attainable standard of health', in the 5th and 6th editions of the *Oxford Textbook of Global Public Health*. We gratefully acknowledge our indebtedness to the co-authors—Gunilla Backman,

Judith Bueno de Mesquita, Louise Finer, Rajat Khosla, Dragana Korljan, and Lisa Oldring—who worked with the current co-author, Paul Hunt, on the chapter in the two preceding editions.

Thanks are also due to Amanda Gray Meral, University of Essex, for her research assistance in preparing this chapter for the 7th edition.

3.4

Law and the public's health

Lawrence O. Gostin

Introduction to law and the public's health

Public health law can be defined as the legal powers and duties of government, in collaboration with multiple partners (e.g. healthcare, business, the community, the media, and academe), to assure the conditions for people to be healthy and safe (to identify, prevent, and ameliorate risks to health in the population). In many countries, there is a constitutional right to health, while in others government has the power to safeguard the public's health. The prime objective of public health law is to pursue the highest possible level of physical and mental health in the population, consistent with the values of social justice (Gostin and Wiley 2016).

Although government needs adequate power to safeguard the public's health, it should not interfere with the civil rights and liberties of individuals without adequate justification. Government therefore has limitations—both legal and ethical—in exercising power that constrains the autonomy, privacy, liberty, proprietary, or other legally protected interests of individuals. Some of the most challenging, and enduring, debates in public health law are the conflicts between individual liberties and the common good.

Public health laws have deep roots in social history, ranging from the ancient use of quarantines at land and at sea, to sanitary laws in the wake of the Industrial Revolution, through to injury prevention, and non-communicable disease (NCD) control in the late twentieth century. Domestic public health laws operate at the local (e.g. municipal codes), state (provincial), and national level. Often, federalist states such as Brazil, Canada, India, and the United States have complex constitutional arrangements between local, regional, and national public health laws.

Domestic public health laws and regulations also intersect with international health law (e.g. the International Health Regulations and Framework Convention on Tobacco Control), 'soft' law (e.g. World Health Organization (WHO) codes of practice and global strategies), and wider international regimes that impact on health (e.g. trade, migration, human rights, and the environment). At the 2019 World Health Assembly, the WHO adopted a Global Action Plan on Migrant Health. This is an area of considerable public health concern as many migrants are excluded from national health systems (Gostin et al. 2019). The complex intersections between local, national, and international law to protect the public's health cannot be overemphasized.

This chapter first examines the powers and duties of government to protect the public's health and safety, together with the limits on its authority to protect a sphere of individual rights and liberties. Second, it explores the central value of public health law—social justice, with particular attention to unconscionable inequalities in health based on socioeconomic status. Third, the chapter examines the statutes and regulations that create public health agencies—defining their mission, powers, funding, and scope. Fourth, the chapter categorizes seven legal 'tools' at the state's disposal to promote the health, safety, and well-being of the population: taxing and spending, the informational environment, the built environment, the socioeconomic environment, direct regulation, indirect regulation, and deregulation. Finally, the chapter turns to how legal interventions can be used to prevent or ameliorate three major health hazards: infectious diseases, NCDs, and injuries (both unintentional and intentional).

Public health: powers, duties, and limits

Governments have the power and duty to safeguard the public's health and safety. The international human right to health, which virtually all countries accept as part of treaty obligations, imposes on governments the primary responsibility for the public's health. In many newer democracies (for example, in Africa and Latin America), national constitutions also guarantee the right to health, as well as other socioeconomic rights such as the right to life and to a safe environment (Friedman and Gostin 2012;

Gostin et al. 2019). Emerging economic powers such as Brazil, India, and South Africa have had robust 'right to health' litigation in their judicial systems. Whether through international law or national constitutions, the state's highest obligation is the defence of the social and economic well-being of the population, with health and security being among the most vital. In most theories of democracy health and security are seen as quintessential aspects of the social contract between individuals and their governments (Walzer 1983).

Beyond socioeconomic rights, virtually all states around the world—older constitutions such as in the United States, newer ones such as in South Africa, and even those without written constitutions such as the United Kingdom—protect civil and political rights—for example, bodily integrity, privacy, liberty, and non-discrimination. At the same time, national constitutions, as well as public health laws, also usually afford individuals civil and political rights, which can constrain the power of ministries to use compulsion. Provided that agencies act for an important public health purpose, and use means that are proportionate to the ends, they can require conformance with publicly established standards of conduct.

Protecting and preserving the public's health and safety is often not possible without constraining a range of private activities that pose unacceptable risks. Private actors can profit by engaging in practices that damage the rest of society: individuals can spread infectious disease; industry has a profit motive, which can result in unsafe workplaces, environmental pollution, or unhealthy foods. Some industries are inherently dangerous (e.g. tobacco), while others can have decidedly harmful effects (e.g. alcoholic beverages). In each instance, individuals or organizations act in their own interests, but their actions may adversely affect communal health and safety. In the absence of governmental authority and willingness to coerce, such threats to the public's health could not easily be reduced.

Although regulation in the name of public health is intended to safeguard the health and safety of populations, it often benefits those most at risk of injury and disease. Everyone gains value from public health regulations, such as food and water standards, but some regulations protect the most vulnerable. For instance, eliminating a toxic waste site, enforcing a building code in a crowded tenement, or closing an unhygienic restaurant holds particular significance for those at immediate risk. Frequently, those at

increased risk are particularly vulnerable due to their race, gender, or socioeconomic status.

Individuals and businesses often oppose government regulation (Reeve and Gostin 2019). Resistance is sometimes based on philosophical grounds of autonomy, choice, or freedom from government interference. Citizens, and the groups that represent them, claim that regulating self-regarding behaviour, such as the use of seat belts or motorcycle helmets, is not the business of government. Or they harbour suspicions about government's intent, such as fluoridation of drinking water or compelled vaccination. Public health agencies sometimes have to defend charges of paternalism, or the 'Nanny State', such as with Mayor Bloomberg's decision to limit portion size of sugary drinks in New York City (Gostin and Gostin 2009).

Public health has historically constrained the rights of individuals and businesses to protect community interests in health. Reporting and surveillance diminish privacy; mandatory testing, vaccination, and treatment invade bodily integrity; environmental standards reduce property values; industrial regulation impedes economic freedom; and isolation and quarantine deprive individuals of liberty. In each of these cases, and more, public health has not shied from regulating individuals and businesses for the common good.

Public health powers can legitimately be used to restrict human freedoms and rights, but they must be exercised consistent with constitutional and statutory constraints on state action. Governments cannot over-reach, such as constraining liberty without sufficient evidence of public benefit. When agencies coerce, they must do so proportionately, such as by using the least restrictive measure needed to avert the health threat. And they must always act fairly, without discrimination on grounds such as race, gender, or disability. Achieving a just balance between the powers and duties of the state to advance the public's health and constitutionally protected rights poses an enduring challenge for public health law.

Social justice

Social justice is viewed as so central to the mission of public health that it has been described as the field's core value: 'The historic dream of public health … is a dream of social justice' (Beauchamp 1999, p. 105). Among

the most basic and commonly understood meanings of justice is fair, equitable, and appropriate treatment in light of what is due or owed to individuals and groups (Rawls 1971). Yet, while many global health indicators have gone up, the 'equity gap' between higher and lower income groups has remained stagnant within and among nations. Brazil, for example, has considerable poverty but yet has enormous income held by the most wealthy.

Social justice captures the twin moral impulses that animate public health: to advance human well-being by improving health and to do so particularly by focusing on the needs of the most disadvantaged (Gostin and Powers 2006). This account of justice has the aim of bringing about the human good of health for all members of the population. An integral part of that aim is the task of identifying and ameliorating patterns of systematic disadvantage that profoundly and pervasively undermine prospects for well-being of oppressed and subordinated groups—people whose prospects for good health are so limited that their life choices are not even remotely like those of others (Powers and Faden 2006). These two aspects of justice—health improvement for the population and fair treatment of the disadvantaged—create a richer understanding of public health law and ethics. Seen through the lens of social justice, the central mission of the public health system is to engage in systematic action to assure the conditions for improved health for all members of the population, and to redress persistent patterns of systematic disadvantage.

Imagine a government policy designed to reduce tobacco consumption in the population. If the government were to lower the smoking prevalence from, say, 30% to 15%, would that be acceptable if marginalized groups such as institutionalized populations (e.g. prisoners and persons with mental illness) continue to have high smoking prevalence? What if the government explicitly targets smoking prevention messages to the well-off but not in poor neighbourhoods? Is that acceptable as a matter of social justice?

These are the quintessential values of public health law—government power and duty, coercion and limits on state power, and the value of social justice. To achieve the goals of population health under the rule of law requires sound legal foundations. Statutes and regulations—as interpreted by the judicial system—establish the infrastructure for public health agencies ranging from their mission, functions, and powers, to their organization and funding.

Public health statutes: legal foundations of public health agencies

The field of public health is typically regarded as a scientific endeavour, and undoubtedly our understanding of the aetiology and response to disease is heavily influenced by technical inquiry. Less well understood is the role of law in public health. Law defines the jurisdiction of public health officials and specifies the manner in which they may exercise their authority. Public health statutes create public health agencies, designate their mission and core functions, appropriate their funds, grant their power, and limit their actions to protect a sphere of freedom. They authorize the collection of health information and enable monitoring and regulation of dangerous activities. The most important public health debates take place in legal forums—legislatures, courts, and administrative agencies—and in the law's language of rights, duties, and justice (Grad 2004).

The quality and modernity of public health laws around the world are highly variable (Institute of Medicine 2011; Gostin et al. 2019). Some states have relatively recent and comprehensive public health laws; others have older statutes, while still others have virtually no public health laws. Overall, public health statutes often have a number of deficiencies. They may be quite old, reflecting an era when infectious and sexually transmitted infections were the major health hazards. They can be highly fragmented, built up in layers over time, for example, beginning with tuberculosis and sexually transmitted infections (e.g. syphilis and gonorrhoea), through to polio and then AIDS, and more recently traffic safety and diet and physical activity. These laws may not afford the state sufficient authority to protect the public's health and safety and they may fail to adequately protect individual rights and freedoms. For example, many older statutes do not ensure natural justice or procedural due process before the exercise of compulsory powers.

Given the importance of sound, modern public health laws, many (if not most) states should examine the corpus of their public health laws and regulations. Low- and middle-income countries may need the capacity and knowledge to reform their laws. The influential Institute of Medicine (now the National Academy of Medicine) in the United States issued a major report on public health law reform in 2011, urging states to adopt the

‘Turning Point’ Model Public Health Act (Hodge et al. 2006). That model act could provide a template for other countries. Additionally, the WHO and partners have developed a report on using law to advance the right to health (WHO 2017). The WHO report offers law reform guidance particularly in low- and middle-income countries.

The WHO Constitution requires member states to notify the organization of its major public health statutes and regulations, even though few states actually comply. The WHO historically published a *Health Law Digest*, but the organization has drastically cut back resources for the *Digest*. The Director-General’s reorganization several years ago removed ‘law’ from the title of the department charged with publishing the *Digest*. Today, the *Digest* is solely in electronic form and has lost its utility to provide a systematic account of national public health laws.

The lawmaking process: building constituencies and forming partnerships

The methods and goals of public health are often misunderstood and undervalued within government and society. Public health needs opportunities to draw attention to its resource requirements and its achievements so that it can develop constituencies for programmes. The lawmaking process provides such an opportunity. A bill is the first step towards a coalition. It is an occasion for contact with interest groups and affected communities, some of whom may be motivated to act in support of the bill. Contacts and collaborative efforts also help to establish long-term ties and identify important sources of support for other programmes. Moreover, the process of negotiating for support can be a useful and concrete way for health agencies to incorporate the views of persons who receive public health services or are subject to regulation.

Legal reform also has the potential to enhance health agencies’ relationships with the legislature. Positive lawmaking offers a different sort of contact with legislators than tends to occur in the appropriations process. Public health law reform may offer an occasion to deal with a far greater range of legislators outside the context of contentious budget discussions. The drafting, negotiating, and hearing processes provide a variety of forums for educating lawmakers and their staffs about public health needs and

methods and also provide health planners with better information about legislative views and priorities.

Law reform, of course, cannot guarantee better public health. However, by crafting a consistent and uniform approach, carefully delineating the mission and functions of public health agencies, designating a range of flexible powers, and specifying the criteria and procedures for using those powers, the law can become a catalyst, rather than an impediment, to reinvigorating the public health system.

Models of legal interventions: law as a tool for the public's health

Law can be empowering, providing innovative solutions to the most implacable health problems. Many of the great public health achievements in the twentieth century were realized, at least in part, through law reform or litigation, including vaccinations, safer workplaces, safer and healthier foods, motor vehicle safety, control of infectious diseases, tobacco control, and fluoridation of drinking water (CDC 2000).

The study of public health law, therefore, requires a detailed understanding of the various legal tools available to prevent injury and disease and to promote the health of the populace. There are a number of models for using law as a tool for the public's health and safety, including: taxation and spending, the informational environment, the built environment, the socioeconomic environment, direct regulation, indirect regulation through the tort system, and deregulation. Although in each case the law can be a powerful agent for change, the interventions can also raise critical social, ethical, or constitutional concerns (Gostin and Gostin 2009).

Model 1: the power to tax and spend

The power to tax and spend—the quintessential governmental function found everywhere—provides government with an important regulatory technique. Most governments invest in a broad array of services to promote public health ranging from surveillance to education and research. Although funding is far too limited, many governments spend to establish and maintain a public health infrastructure consisting of: a trained workforce;

electronic information and communications systems; rapid disease surveillance; laboratory capacity; and response capability. In some states, governments can attach ‘conditions’ to public spending that are intended to be health promoting. For example, in the United States, the federal government requires states to have a drinking age of 21 years as a condition of the receipt of highway funds. Yet, in 2012, the US Supreme Court on the Affordable Care Act (ACA) ruled that the federal government cannot constitutionally require states to expand Medicaid as a condition of funding. In the ACA, Congress had authorized the Department of Health and Human Services to withhold all Medicaid funding if states did not expand Medicaid. The Court ruled that was too ‘coercive’ (*National Federation of Independent Business v. Sebelius* 2012).

The power to tax is primarily designed to raise revenue, but it also can provide significant inducements to engage in beneficial behaviour and disincentives to engage in risk activities. Tax relief can be offered for health-producing activities such as healthcare services, childcare, and charitable contributions. At the same time, tax burdens can be placed on the sale of hazardous products such as cigarettes, alcoholic beverages, and firearms. The WHO Framework Convention on Tobacco Control, for example, supports high taxes on tobacco products. A tax on sugar sweetened beverages has also been shown to reduce consumption of calorie-laden beverages (Gostin 2018; Roache et al. 2016). Of course, taxation can create perverse incentives such as tax relief for the purchase of unsafe and fuel-inefficient motor vehicles. A carbon tax offers a good example of an economic vehicle that would be beneficial to the public’s health and the environment.

Model 2: the power to alter the informational environment

The public is constantly exposed to images and information that influence their life choices, and this undoubtedly affects health and behaviour. The reliability and usefulness of information is variable. Some messages are educational, such as child nutrition campaigns. Other information can be biased—either inaccurate or misleading. For example, the corporate profit motive can result in advertisement of harmful products, such as foods with excess sugar and salt. Messages such as ‘low fat’, ‘low calorie’, or ‘light’ can be confusing or deceptive.

Regulating the flow in information can be challenging. In practical terms, governments do not have the available resources to compete with large advertising budgets that market unhealthy foods, alcoholic beverages, or tobacco. In constitutional terms, there can be questions about whether advertising restrictions violate the corporation's right to free expression.

Governments have several tools at their disposal to alter the informational environment thereby encouraging people to make more healthful choices about diet, physical activity, tobacco, and alcohol. First, government, as a health educator, can use communication campaigns that warn consumers of high risks (e.g. smoking or driving while intoxicated) or encourage safer activities (e.g. wearing seat belts or motorcycle helmets). Second, government can require businesses to label their products to inform consumers: instructions on safe product use, disclosure of contents or ingredients, or warnings about hazards. Third, government can regulate advertising and promotions for potentially harmful products such as cigarettes and firearms. They can also limit marketing certain products to vulnerable populations, such as children and adolescents.

Regulating tobacco packaging and advertising offers a good illustration. The WHO's Framework Convention on Tobacco Control (WHO 2005a) requires states to adopt supply and demand reduction strategies, including advertising restrictions. Yet, the tobacco industry has challenged advertising restrictions and packet labels in countries as diverse as Australia, Uruguay, and the United States. Australia was the first country to introduce plain packaging legislation with graphic images of the harms of tobacco. Australia's highest court upheld the legislation, and the government won both in an international Investment Treaty dispute and the World Trade Organization challenge (*British American Tobacco Australia Limited v. The Commonwealth* 2012). Uruguay's tobacco control legislation was also being challenged in a separate Investment Treaty case (*FTR Holding v. Oriental Republic of Uruguay* 2010). The tribunal also ruled in favour of Uruguay. 'Big Tobacco' is claiming that the state is unfairly 'taking' their property or diminishing the value of their private investments. Although this may seem to be an outrageous claim, it is expensive for states to defend their public health laws (Roach et al. 2016).

In the United States, the Food and Drug Administration's requirement of graphic warning labels was put on hold following a court ruling. Tobacco companies are claiming that the graphic image requirement violates their

rights to free expression (*R.J. Reynolds Tobacco Company v. Food and Drug Administration* 2012). The United States is one of the world's outliers in that its highest court ardently defends the right of corporations to free expression, thus thwarting public health restraints on advertising hazardous products.

Model 3: the power to alter the built environment

The design of the 'built' or 'physical' environment can hold great potential for creating healthier and safer communities. Public health has a long history of altering the built environment to reduce injuries (e.g. workplace safety, traffic calming, consumer protection, and fire codes), infectious diseases (e.g. sanitation, nuisance abatement, and housing codes), and environmentally associated harms (e.g. lead paint and toxic emissions). Sanitary laws go back hundreds of years, designed to ensure more hygienic conditions in growing cities; occupational health and safety became prominent following the Industrial Revolution, which exposed workers to toxins and unsafe working conditions; and more modern laws provide patients and consumers with protection against unsafe products.

The epidemiological transition from infectious to chronic diseases raises new challenges in the design of neighbourhoods. For example, urban design can encourage more active lifestyles (walking lanes, bicycle paths, parks, green fields, and playgrounds); improve nutrition (zoning to limit fast food); discourage the use of hazardous products ('tobacco-free' indoor spaces); reduce violence (well-lit streets, safe storage of firearms); and increase social interactions (helping neighbours and building social capital) (Perdue et al. 2003).

Many zoning laws in the mid and late twentieth century were unfavourable to healthy lifestyles, such as those giving preference to motor vehicles over pedestrians and bicycle riders, or preferring commercial development over playgrounds. Municipalities often facilitated the expansion of unhealthy fast foods, forming 'food deserts' in poor neighbourhoods. These are political choices, and debates still rage over whether government should use health as a major factor in designing living spaces, rather than, say, economic development. What seems certain is that it is within the power of government to structure the environment in ways that are more conducive to a healthy diet and physical activity.

Model 4: the power to alter the socioeconomic environment

A strong and consistent finding of epidemiological research is that socioeconomic status (SES) is correlated with morbidity, mortality, and functioning (Marmot 2005). SES is a complex phenomenon based on income, education, and occupation. The relationship between SES and health often is referred to as a 'gradient' because of the graded and continuous nature of the association; health differences are observed well into the middle ranges of SES. These empirical findings have persisted across time and cultures and remain viable today.

Some researchers go further, concluding the overall level of economic inequality in a society correlates with (and adversely affects) population health. That is, societies with wide disparities between rich and poor tend to have worse health status than societies with smaller disparities, after controlling for per capita income. These researchers hypothesize that societies with higher degrees of inequality provide less social support and cohesion, making life more stressful and pathogenic. Drawing upon this line of argument, some ethicists contend, 'social justice is good for our health' (Daniels et al. 2000).

The WHO issued a report on social determinants of health, urging more attention to the underlying factors in influencing health outcomes (WHO 2008b). However, the WHO never put significant resources into social determinants and did not follow the Commission Report with international law or softer norms. From government's perspective, ensuring a healthy population that is fair and equitable requires an 'all of government', indeed 'all of society' approach that transcends the health sector.

Although social determinants powerfully affect health, they can require redistribution of wealth and hence are often hotly contested. Opponents of redistributive policies argue such policies punish personal accomplishment, thereby discouraging economic growth. Still, it is impossible to make significant inroads into health disparities without careful attention to the deeper social and economic determinants of health.

Model 5: direct regulation of persons, professionals, and businesses

Government has the power to directly regulate individuals, professionals, and businesses. In a well-regulated society, public health authorities set clear, enforceable rules to protect the health and safety of workers, consumers, and the population at large.

Regulation has long been a staple of injury control. In most Western countries, for example, the rate of motor vehicle-related injuries and deaths has plummeted due to law reform. Governments required individuals to engage in safer behaviour, such as by using seat belts and motorcycle helmets. The law also compelled manufacturers to design and sell safer vehicles, such as cars with airbags and with the ability to better withstand crashes. The law also set standards for governmental and commercial development such as safer roads and traffic calming. Yet, with the explosion of motorized vehicles in newly emerging states, the injury and death rates from motor vehicles are alarming. The streets of Bangkok, Delhi, and Hanoi (among many others) are teeming with unsafe vehicles, chaotic roads, and motorcycle drivers and passengers without helmets.

Perhaps the most ancient use of direct public health regulation is in the control of infectious diseases. Governments often mandate vaccination, screening, partner notification, directly observed therapy, and isolation or quarantine. Originating from the ancient scourges such as leprosy, malaria, and tuberculosis, through to syphilis and herpes, and to the modern AIDS pandemic, states—for good or bad—have enacted civil and criminal laws to deter or punish perceived risk behaviours. Early in the AIDS pandemic, for example, many states enacted laws to require testing (e.g. prisoners), travel and immigration restrictions, and even quarantine (e.g. Cuba). Criminal laws were altered to punish behaviours conducive to transmitting HIV, and to targeting risk populations such as injecting drug users and commercial sex workers.

Direct regulation also plays a major role in ensuring that professionals and businesses operate safely and with the requisite level of skill and knowledge. Licences and permits enable government to monitor and control the standards and practices of healthcare professionals, hospitals, and nursing homes. By licensing and accrediting health professionals, public health agencies can help ensure safe, competent, and well-qualified practitioners. Finally, inspection and regulation of businesses helps to assure humane conditions at work, reduced toxic emissions, and improved consumer product safety.

The control of chronic diseases is becoming the new battle-ground over the wisdom of direct regulation. Some jurisdictions have banned harmful ingredients such as trans fatty acids; others have reduced harmful additives, such as excess sugar or sodium; while still others have regulated portion size, such as the size of a sugary soft drink. Recent research suggests, 'sugar is toxic', which may require public health agencies to set or recommend safer levels of sugar intake (Basu et al. 2013).

When regulating what people eat or their physical activity, governments often face the stinging criticism that they are acting paternalistically, with the charge of running a 'Nanny State'. To public health advocates, these are all necessary measures to make health the 'easier' or 'default' choice. But to many in society, it restricts their freedoms to make their own decisions about their health and well-being (Gostin and Gostin 2009).

Model 6: indirect regulation through the tort system

Ministries of justice and health, as well as private citizens, possess a powerful means of indirect regulation through the tort system. Civil litigation can redress many different kinds of public health harms: environmental damage (e.g. air pollution or groundwater contamination), exposure to toxic substances (e.g. pesticides, radiation, or chemicals), hazardous products (e.g. tobacco or firearms), and defective consumer products (e.g. children's toys, recreational equipment, or household goods).

The most prominent illustration of using judicial remedies for a public health purpose is tobacco litigation. Tort litigation against the tobacco industry began in the United States. This litigation had multiple benefits. It resulted in a 'Master Agreement' between states and tobacco companies, with large sums given to states. It uncovered highly damaging evidence about the deceptive behaviour of the industry, such as raising the nicotine level of cigarettes, hiding information about the hazards of smoking, and targeting young girls, racial minorities, and minors with cigarette advertisements and promotions.

More modern litigation has been waged under the constitutional right to health in places such as India and Latin America. Public health advocates in these and other countries have sued tobacco companies for knowingly misleading the public. They have also sued their own governments to force

them to adopt more rigorous tobacco control measures, such as clean air acts (Cabrera and Gostin 2011).

Perhaps it would be predictable for Big Tobacco to use the law as a sword against government regulation. Increasingly, the industry is using the constitutional right to property or commercial speech, bilateral investment treaties to safeguard their investments, or World Trade Organization treaties to stall or block tobacco control (Mitchell and Studdert 2012).

Using tobacco litigation as a model, public health advocates have sought to use tort law to attack the deceptive and harmful practices of other powerful industries. This litigation ranges from lawsuits against the food industry (e.g. marketing unhealthy products to minors), the firearms industry (e.g. trafficking in dangerous weapons), and the alcohol industry (e.g. glamorizing underage or excessive drinking). Thus far, most of these lawsuits have not been successful. One difference is that food, firearms, and alcoholic beverages when used responsibly are not harmful, while tobacco use is always hazardous.

To what extent should the harmful activities of these and other industries be immune from tort litigation on the theory that autonomous consumers are free to make their own decisions—whether healthful or harmful? Given that individuals are embedded in communities and societies that profoundly affect their personal choices, laws should enable consumers to litigate if the private sector has exposed them to unnecessary and serious risks.

Model 7: deregulation: law as a barrier to health

Sometimes laws are harmful to the public's health and stand as an obstacle to effective action. In such cases, the best remedy is deregulation. Politicians may urge superficially popular policies that have unintended health consequences. Consider laws that prohibit or penalize needle exchange programmes and pharmacy sales of sterile syringes. Even though access to sterile injection equipment significantly reduces the risk of needle-borne infections (e.g. HIV and hepatitis B or C) and does not encourage illicit drug use, many governments discourage or ban the distribution of these products, including by public health agencies.

A further illustration is the decision to close bathhouses, making it more difficult to reach gay men with condoms and safe sex literature. Rather than

banning these activities, government could use them as venues for education and harm reduction.

Finally, but perhaps even more importantly, governments throughout the world criminalize high-risk activities. They punish sex workers, drug users, and even those who engage in same-sex sexual activities. Criminal laws that punish activities that risk transmission of HIV, for example, do not appear to reduce unsafe behaviour, but rather drive the epidemic underground.

Criminal law is usually a blunt, ineffective, and unfair tool when used for an allegedly public health purpose. Deregulation, however, can be controversial because it often involves a direct conflict between public health and other values that society may favour, such as crime prevention or morality. Drug laws, the closure of bathhouses, and HIV-specific criminal penalties represent society's disapproval of disfavoured behaviours. Deregulation becomes a symbol of weakness that is often politically unpopular. Public health advocates may believe passionately in harm-reduction strategies, but the political community may want to use the law to demonstrate social disapproval of certain activities such as illicit drug use, commercial sex, or unprotected sex.

The government, then, has many legal 'levers' designed to prevent injury and disease and promote the public's health—taxing and spending, the informational environment, the built environment, the socioeconomic environment, direct regulation, indirect regulation, and deregulation. Legal interventions can be highly effective and need to be part of the public health officer's arsenal. However, legal interventions can also be controversial, raising vital ethical, social, constitutional, and political concerns.

Enforcing public health laws

Law on the books that promotes the public's health is important, but it has little utility if it is not well implemented and enforced. Enforcement is a problem in all countries, but particularly many low- and middle-income countries (LMICs). Enforcement in LMICs can be impeded by many forces, such as lack of political will, corruption, and lack of legal capacities. All governments should make implementation of public health laws a high priority because enforcement is needed to secure the common good. This will require tackling corruption and funding capacity building. The South

African Constitutional Court required an anticorruption mechanism that was badly needed for holding public officials accountable. Legal capacities include well trained legislators, judges, public health officials, inspectors, and others who can ensure that laws are implemented rigorously but fairly.

Case studies of four major health hazards

The previous sections often used major health hazards as illustrations of the use of public health law. This chapter concludes with four brief case studies: infectious diseases, NCDs, unintentional injuries, and violence to self or others. This final section shows how the intersection between public health law at the local, national, and international levels can influence health outcomes.

Infectious disease law

As mentioned earlier, infectious disease law has ancient origins (Markel 2005). Epidemic disease has historically had profound implications, not only for animal and human health, but also for security, trade, tourism, and social relationships. Infectious diseases often bring out the worst in people and societies, provoking stigma and discrimination against disfavoured groups such as immigrants and ethnic or religious minorities. Rapidly emerging diseases (such as novel influenzas) often provoke unjustified trade or travel restrictions. At the same time, governments are likely to spend disproportionate public health resources on highly transmissible or novel infections—disproportionate at least insofar as infectious pathogens receive so much more attention than equally destructive health hazards, such as NCDs, injuries, and mental illness.

This dynamic can be seen in the emphasis in domestic and international laws on infectious diseases. The oldest international health law—dating from mid-nineteenth-century sanitary conferences in Europe—is the International Health Regulations, which are devoted almost exclusively to health security. The first time the International Health Regulations (WHO 2005b) was used was in relation to the influenza A (H1N1) pandemic. In total, WHO has declared the following emergencies under the IHR: swine flu (2009), polio (2014), Ebola (2014), and Zika (2016). As of June 2019,

WHO has not declared an emergency in response to the Ebola epidemic in the Democratic Republic of Congo.

The emphasis on epidemic diseases can also be seen in domestic law, where most public health statutes are devoted to infectious disease powers, such as testing, screening, partner notification, directly observed therapy, and isolation or quarantine. During the SARS outbreaks, states—particularly in North America and Asia—exercised public health powers extensively including travel restrictions, trade barriers, border security, and quarantine (Fidler 2004). When the Republic of Korea experienced a major Middle Eastern Respiratory Disease outbreak in 2015, it also exercised extensive powers.

Even in the realm of international relations, infectious diseases have dominated funding and political attention. The AIDS pandemic fundamentally changed the political and funding calculus for global health. The United States launched the greatest effort by a single country against a single disease—PEPFAR. The United Nations (UN) formed a new agency to coordinate work on AIDS—UNAIDS. And powerful new public/private partnerships emerged to provide unprecedented funding for work on AIDS, tuberculosis, and malaria, such as the Global Fund and UNITAID, while the GAVI Alliance supports another infectious disease initiative—immunizations. Most impressively, the international community has vastly ramped up research, funding, and access to antiretroviral treatment for HIV/AIDS. AIDS law at the national level can be highly impactful. Laws, from Africa and Asia to Europe and the Americas can ensure access to treatment, while combatting non-discrimination.

Following the West Africa Ebola epidemic in 2013–16, the WHO fundamentally reformed it health emergency capacities, including a new programme and an emergency contingency fund (Gostin et al. 2016).

Non-communicable disease law

Four NCDs—cardiovascular disease, cancer, respiratory disease, and diabetes—account for 63% of global deaths annually. The conventional wisdom, which conceives of NCDs as a ‘First World’ problem, is starkly belied by data: 80% of the 35 million people who die annually from NCDs live in LMICs. The death toll is projected to rise by 17% over the next decade, unless meaningful steps are taken urgently. With the exception of

sub-Saharan Africa, NCD mortality now exceeds that of infectious, maternal, perinatal, and nutritional conditions combined (WHO 2011).

The suffering and early deaths from NCDs, and the disproportionate burden in lower-income countries, will only grow. And they will interact with existing health challenges in poorer countries, creating the ‘double burden’ of hunger alongside obesity. Although longer lifespans partly explain the increased burden of NCDs, human behaviour plays a central role: unhealthy diets, sedentary lifestyles, smoking, and excessive alcohol consumption account for more than two-thirds of all new NCD cases.

The moral tragedy lies in the fact that much of this suffering and early death is preventable, and many of the solutions are to be found in law—at both the domestic and international levels. Local and national governments have all the public health law tools at their disposal in fighting the NCD epidemic. They can tax unhealthy products such as tobacco, alcoholic beverages, sugary drinks, and sodium-laden processed foods. Equally, rich states could cease subsidizing unhealthy foods, such as high-fructose corn syrup, cane sugar, and even red meat and dairy, while subsidizing healthy fruits and vegetables.

Governments can also alter the informational environment, counteracting incessant commercial messages—for example by package labelling, health warnings on cigarettes and alcohol, and comprehensible nutritional information on food packages and restaurant menus. The United Kingdom Food Standards Agency developed a voluntary system ‘traffic light’ system that is visible and simple to follow. By putting a series of bright red lights on food packages with excessive saturated or trans fats, sodium, sugar, and calories, it incentivizes food companies to be more responsible, while clearly informing consumers. The state can restrict advertising unhealthy products, particularly when aimed at minors (Hawkes 2007).

Individual choices are not made in isolation but reflect the environment in which people live. Government could use its powers to plan cities and zones to facilitate healthy lifestyles, including supermarkets and farmers’ markets. It can build bike and walking paths, designate pedestrian areas, subsidize mass transit, and discourage motor vehicle use—such as the ‘congestion tax’ instituted by the city of London in the United Kingdom. Government could require ‘health impact assessments’ as a condition of new government or commercial development.

Although incentives and voluntary approaches are often more politically palatable, there is also a role for direct regulation. Some products, such as trans fatty acids, are so hazardous to health that they should be removed from the market, as Denmark has done (see Table 3.4.1).

Table 3.4.1 Domestic strategies to address NCD risk factors

Domain	Goal	Intervention	Example
Healthy lifestyles	Optimal nutrition	Agricultural production Food manufacturing, processing, and distribution	Incentives to produce healthier foods Regulation of food industry and retailers
		Disincentives for buying and selling unhealthy food	Fat tax
		Marketing unhealthy foods	Restricting advertisements targeting children
		Nutritional information disclosure and education	Providing government nutritional guidelines; improving package labelling; menu labelling
		Direct regulation	Banning unhealthy ingredients (such as trans fats)
		Public–private partnership	Voluntary targets for nutritional values
	Physical activity	Incentives for exercise	Subsidies for physical exercise and organized activities
		Flexible spending accounts	Corporate allowances for fitness activities
		Monitor community physical activity	Public health surveillance of monitoring prevalence of NCDs
Healthy places	Places to buy and eat Food	Access to affordable, healthy foods	Farmers' markets; zoning of unhealthy fast foods
		Healthy foods in schools, workplaces, etc.	Vending machines, snacks, meals
		School/childcare curricula and programmes	Body mass index (BMI) surveillance; nutrition education
	Places to walk, recreate, and play	Workplace/education settings and programmes Urban land use and planning	Organized activities; fitness memberships Attractive, accessible, safe public places and paths
		Tax incentives for building design	Businesses incorporating building designs that promote physical activity
		Transportation	Mass transit and safe routes

Domain	Goal	Intervention	Example
		Health impact assessments	Consultation with affected communities; public health evaluations
Healthy societies	Social justice	Antidiscrimination laws	Proscribe medical condition-related discrimination
	Access to services	Services to support life functions of ill individuals	At-home support services
		Encourage prevention and treatment	Metabolic screening; counselling
		Monitoring disease in the community	Surveillance through BMI reporting

It is equally important to marshal a transnational response. The impact of globalization—globalized food and tobacco markets and the homogenization of cultures and behaviours—means that no country can effectively tackle NCDs without the support and cooperation of the international community. Global governance for health requires a multifaceted approach (Gostin 2014). The international community could set norms for healthy activities, such as the Framework Convention on Tobacco Control (WHO 2005a). The WHO has also developed 'global strategies' covering: NCD prevention and control (2000); diet, physical activity, and health (2008); and the harmful use of alcohol (2010). In 2008, the Assembly adopted the 2008–2013 Action Plan for its Global Strategy on NCDs, and in 2010, it adopted recommendations on the marketing of foods and non-alcoholic beverages to children (WHO 2008a, 2010).

The decade of WHO governance on NCDs failed to raise NCDs to the same high profile and impact as HIV/AIDS. But the UN General Assembly (2011) hosted a high-level meeting on NCDs in September 2011, adopting a *Political Declaration on the Prevention and Control of Non-Communicable Diseases*—a 65-point document, cataloguing many of the global challenges, and calling for a whole-of-government/whole-of-society response. Broadly speaking, the Declaration recommends preventative measures, health system strengthening, international cooperation, research and development, and monitoring and evaluation of progress. Sadly, however, the UN failed

to set clear targets, a tangible road-map to meet those targets, and the resources needed to tackle the global NCD pandemic.

Just as domestic governments need to adopt an 'all-of-government/all-of-society' approach, so too must global institutions look beyond WHO to a more expansive view of governance. In short, there is a need for 'total global engagement', encompassing trade, investment, development, intellectual property, and human rights—all international law regimes in their own right. The private sector is a vital part of the solution, but the major companies operate all over the world, so corporate governance must also operate at the global, as well as the national, level.

Injury control law

Injuries are often portrayed as 'accidents' or 'random events' that are unpredictable and therefore unpreventable, as opposed to a serious public health concern, which explains the field's historical neglect. However, injuries are a leading cause of death and disability worldwide, resulting in nearly 6 million deaths annually and representing 17% of the global burden of disease; by 2020 the global burden of injuries is projected to increase to 20% (WHO 2011). The injury epidemic has been compounded by rapid unplanned urbanization, increased motorization, and dramatic changes in the built environment in LMICs (Lozano et al. 2012; Murray et al. 2012; Salomon et al. 2012).

There are marked inequalities in the global distribution of injuries, with >90% of all deaths and disability-adjusted life years occurring in LMICs, mostly among young people. The economic burdens for those countries are staggering: traffic incidents alone cost $65 billion or 1–1.5% of GDP annually (Norton et al. 2006).

The WHO differentiates between unintentional injuries (no predetermined intent such as road traffic incidents, poisonings, falls, fires, and drowning) and intentional injuries (self-directed such as suicide or self-mutilation, interpersonal such as domestic violence or murder, or collective violence such as war-related injuries). Law reform can help prevent both of these.

The UN Convention on the Rights of the Child (UN 1989) guarantees all children the right to a safe environment and to protection from injury and violence. Yet, injuries are the single greatest cause of death and disability

among children in LMICs. Drowning is a leading cause of morbidity and premature mortality in children under 5 years of age. With increasing age, mortality resulting from road traffic crashes surpasses that from drowning, with traffic deaths being the greatest overall killer of children aged 15–19.

Men often suffer injuries in the course of paid labour or occupational pursuits, while women suffer burns as a result of their customary domestic role—in the kitchen, from fires or scalding water, and as a result of cooking on open fires. The home use of kerosene or paraffin lamps, which are easily knocked over and ignited, is also a large contributor. Above all, underlying gross poverty heavily influences many of these injuries, irrespective of age and gender.

National public health laws are perhaps the single most potent interventions to prevent injuries. Developed countries have used a multitude of regulations to vastly curtail traffic injuries and deaths—e.g. driving licences, speed limits, vehicle safety, motorcycle helmets, and road design. For example, when Viet Nam passed and enforced a law requiring helmet use for motorcycles, the number of head injuries declined dramatically (WHO et al. 2017). Yet, in many LMICs, the roads are chaotic and very dangerous, with vehicles unfit for travel and roads poorly planned. The mix of pedestrians, bicycles, and motorized vehicles on unsafe roads that do not separate the types of traffic is lethal. To further compound the problem, roadways are usually designed with the convenience of the drivers in mind and little thought for the safety of pedestrians. In Nairobi, residents of Kibera, one of the largest urban slums in the world, suffer inordinate road traffic injuries and deaths, as they have to run across dangerous roads to get to work, school, or shops to buy food and clothing.

Work-related injuries are ubiquitous in low-resourced countries. The rise in industrial development and the lack of attention to safety will ensure that occupational injuries double by 2025. Again, this situation is very different in the developed world, which has steadily decreased occupational injury rates over the years. Most industrial work in low-resourced countries such as agriculture, manufacturing, and mining is already associated with high rates of injury from electrical, mechanical, and physical hazards. Now, the steady expansion of chemical and biotechnology industries has introduced new injury risks.

Yet, occupational health and safety laws cover only 10% of the population in low-resourced countries. Without adequate regulations,

businesses do not invest in quality equipment or train workers to ensure safety. Companies often expect workers to take inordinate risks because labour is cheap and plentiful. If developing countries do not soon implement effective safety standards, the health costs to workers in high-risk jobs will outweigh the financial benefits of industrial development.

Intentional injuries are also a vast and growing problem, particularly in LMICs. Rates of robberies, assaults, rapes, and homicides can be devastating in major cities such as Johannesburg. India has experienced an epidemic of gender-related violence, which also occurs in many other parts of the world. In some African countries, gay men are subjected to brutal assaults and murders. Yet, it is possible to prevent most injuries through technological innovation, safety regulation, and law enforcement. However, the same ingenuity and resources that make the home, workplace, and the streets safer in richer countries have not been applied in low-resourced countries. The WHO devotes <1 per cent of its budget to injuries and violence.

Developed countries, of course, are not immune from violence, which could be dramatically lowered with sound firearm regulation and enforcement. In the United States, for example, firearm-related deaths are roughly equal to road traffic deaths, with few checks on gun buyers or the lethality of weapons and bullets.

If the public health community wishes to close the ‘injury gap’ between rich and poor, it will have to devise evidence-based solutions, demonstrate their effectiveness, engage the private sector, gain the cooperation of police and the courts, devote the resources, and advocate for strong occupational health and safety laws throughout the developed world.

Conclusion: the future of public health law reform

This chapter has sought to demonstrate the powerful potential of law to prevent injuries and disease. Law can build the infrastructure of public health agencies, ensuring a broad mission and adequate powers. It can protect individuals from excessive or unjustified coercion or discrimination. It can promote social justice by narrowing health disparities. At the same time, government has multiple legal tools available to improve the public’s health and safety, ranging from its economic power to tax and spend, to its

authority to alter the environments in which people live (e.g. informational, built, and socioeconomic), through to direct and indirect regulation, including, where necessary, deregulation.

With the potential for rapid dissemination of pathogens, products, services, and marketing throughout the world, the need for global governance cannot be overstated. No country acting alone can stem the tide of injuries and disease. Global health leadership could establish health-promoting norms, set benchmarks, monitor progress, and encourage compliance by state and non-state actors. Global leadership, moreover, must act beyond the health sector, engaging legal regimes such as trade, intellectual property, food, migration, and the environment.

When law is used in a systematic and coordinated way at the local, national, and international levels, it can go a long way towards preventing infectious diseases, NCDs, and injuries (both unintentional and violence-related). For public health practitioners, the lesson is to effectively use the battery of legal tools at their disposal. And when those tools are inadequate, public health agencies must work with civil society and communities to raise the level of political awareness. In a complex and globalized world, public health is a deeply legal and political pursuit—well beyond purely science and technology.

Health policy in developing countries

Thein T. Htay, Yu Mon Saw, James Levinson, S.M. Kadri, Ailbhe Helen Brady, Cecilia S. Acquin, and Aung Soe Htet

Introduction

A strong health policy is an essential platform for the formation of a comprehensive health system in developing countries. Three essential purposes of such a policy are (a) assuring adequate and accessible health services; (b) encouraging responsiveness by the country's population; and (c) protecting the population against health-related catastrophes (WHO 2000). Such a health policy, in turn, is dependent on responsible governance and adequate financial resources.

International health policies focused primarily on communicable diseases (HIV, Tuberculosis and Malaria), non-communicable diseases (NCDs), and maternal and child health problems. In addition, attention is given to malnutrition, problems of drug resistance, mental illness, and chronic NCDs.

Invariably, economic, social inequalities, and often cultural differences existing in developing countries result in poor health status among the disadvantaged, but also, increasingly, chronic NCDs including heart disease, hypertension, stroke, and diabetes along with a growing epidemic of obesity, these problems not limited to industrialized countries.

An increasing number of countries have undertaken health sector reform involving an integrated stewardship process based on a decentralization of healthcare services and the inclusion of social insurance or protection. Accordingly, such stewardship and high standards of governance are essential to effective health policies.

Such policies and the programmes emanating from them require rigorous monitoring and evaluation. China has been successful in decentralizing responsibility and services to local government entities, yet these local governments have generally failed in their monitoring and evaluation

responsibilities. By contrast, Mexico, which also has implemented health sector reform, has been successful in integrating monitoring and evaluation mechanisms into these systems.

The stages of health transition

With decreasing infant and child mortality and improved disease control in many countries, the proportion of elderly persons in these countries has increased (UNFPA 2017). Changes also have been observed in the patterns and causes of death in many countries, with the burden of NCD increasing (WHO 2017). These have been accompanied by the 'nutrition transition' now taking place both in industrialized and developing countries, with countries as diverse as India, China, Brazil, and Russia facing both under- and overnutrition problems (Kapoor and Anand 2002; de Neuezer et al 2001). As a result, health policies and programmes are evolving to tackle these emerging health needs (Martens 2002).

The health transition includes what have been called demographic and epidemiologic transitions (Omran 1998). (The ecological and economic transitions which often accompany health transitions are not included in this article.)

The demographic transition describes changes over time in fertility and mortality rates (Notestein 1945; Demeny 1968; Borgerhoff 1998).

The epidemiologic transition describes the changes in mortality and morbidity patterns (moving increasingly from infectious to chronic NCDs) relative to socio-demographic and economic changes (Omran 1971). Epidemiologic transition theory includes three models: (a) the 'western or classical model' (e.g. Western Europe and Northern America), (b) the 'accelerated model' (e.g. Japan and Eastern Europe), and (c) the 'delayed or contemporary model' (e.g. most developing countries) (Omran 1998).

Overall, the health transition, internationally, has evolved through the following three stages:

Stage I, 'The Age of Pestilence and Famine' was characterized by high and unstable mortality that impedes population growth. During this stage, average life expectancy at birth was low and inconstant, ranging from 20 to 40 years (Omran 1971). The stage was characterized by a high prevalence of infectious diseases and high rates of undernutrition. Women of childbearing age were prone to pregnancy-related illnesses and more vulnerable to

tuberculosis. Epidemics such as plague, cholera, and smallpox were often managed by isolation and quarantine measures as experienced in the late seventeenth century in several European cities (Goudsblom 1986), and these measures also became common in addressing contagious diseases, with rules adopted for trade quarantine and isolation of the sick in US port cities in the eighteenth century. A law for isolation of smallpox patients and for ship quarantine was enforced beginning in 1701 in Massachusetts (Hanlon and Pickett 1984). The recording and reporting of deaths by the plague and other diseases were established in the late seventeenth century (Goudsblom 1986).

With increased urbanization in the nineteenth century, infectious diseases like smallpox and tuberculosis spread easily. Under-five mortality rates were particularly high. During this stage of health transition, public health measures against infectious diseases were developed, and hospitals for physical and mental illnesses were established in the US in the eighteenth century (Turner 1977). Information on health issues facing developing countries during this stage was limited.

In Stage II, 'The Age of Receding Pandemics', we see a significant reduction in mortality. Infectious disease epidemics were less common and sometimes eliminated. Life expectancy at birth increased to 30–50 years. As a result, population growth rates increased significantly. In the early phase of this stage, endemic, parasitic and nutrition deficiency-related diseases, and maternal and child health problems were the leading causes of death (Caldwell 2001). During the nineteenth century, sanitation and personal hygiene improved markedly as increasing numbers of people better understood the causality of infectious diseases and their modes of transmission (Winslow 1923). Although epidemics remained a public health problem, infectious disease control measures evolved from quarantine and isolation to prevention, e.g. personal hygiene and environmental sanitation. Environmental sanitation including waste and sewage disposal and sanitation promotion was adopted in the UK by the Public Health Act of 1848 (Chave 1984).

At the same time in the US, comprehensive public health systems evolved from initiatives such as Shattuck's Report of the Massachusetts Sanitary Commission (Winslow 1923; Rosenkrantz 1972), and boards of health and state health departments began to be established shortly thereafter (Hanlon and Pickett 1984; Fee 1987).

Industrialization, however, became an increasingly prevalent mode of transmission for infectious diseases (Wohl 1983). Although sanitation improved, death from urbanization-related diseases, particularly tuberculosis, increased, as seen in the state of Massachusetts (Hanlon and Pickett 1984). By late in the nineteenth century, however, bacteriology, the germ theory, and laboratories to investigate the causes of infection were being developed in the United States (Winslow 1923). And mortality due to such infectious diseases as yellow fever and typhoid were significantly reduced by improved water sources and sanitation and through an understanding of the concept of vector-borne diseases (Winslow 1923; Blakes 1956).

Stage III 'The Age of Degenerative and Man-Made Diseases' is characterized by declining mortality together with low fertility, resulting in a population pyramid change and a higher proportion of elderly persons. In Stage III, life expectancy at birth increases, on average, to more than 70 years (Omran 1998). In developing countries increased attention is given to tuberculosis. In developed countries, increased attention is given to chronic NCDs and cancer. In the United States, the Food and Drug Act was passed in 1906, the National Institute of Health (NIH) was established in 1930, the National Cancer Institute in 1937, and the Social Security Act was passed in 1935.
